The Epistemic Closure Principle

Most of us think we can always enlarge our knowledge base by accepting things that are entailed by (or logically implied by) things we know. The set of things we know is closed under entailment (or under deduction or logical implication), which means roughly that we know anything that follows from what we know. However, some theorists deny that knowledge is, in fact, closed under entailment, and the issue remains controversial. One might speak of two main camps: those who take closure as a firm datum -- as obvious enough to rule out any understanding of knowledge that undermines closure; and those who want to resolve the controversy by analyzing knowledge and working out the implications for closure. The matter is important, not just because of its bearing on the analysis of knowledge, but also because some theorists say that rejecting the closure principle is the key to defeating skepticism.

---

1. Is Knowledge Closed Under Entailment?

Precisely what is meant by the claim that knowledge is closed under entailment? One response is that the following straight principle of closure of knowledge under entailment is true:

> If person *S* knows *p*, and *p* entails *q*, then *S* knows *q*.

However, the straight principle is obviously false, since we can know one thing, *p*, but fail to see that *p* entails *q*, or for some other reason fail to believe *q*. Since knowledge entails belief (according to nearly all theorists), we fail to know *q*. A less obvious worry is that we might reason badly in coming to believe that *p* entails *q*. Perhaps we think that *p* entails *q* because we think everything entails everything, or because we have a warm tingly feeling between our toes.

Obviously, the straight principle needs qualifying, but this should not concern us so long as the qualifications are natural given the idea we are trying to capture, namely, that we can extend our

knowledge by recognizing, and accepting thereby, things that follow from our knowledge. The qualifications embedded in the following principle seem natural enough:

> If *S* knows *p*, and believes *q* by recognizing that *p* entails *q*, then *S* knows *q*.

If we continue in this way, qualifying the closure principle to handle counterexamples, can we finally devise a version that is true?

1.1 Tracking and Closure

Perhaps, but Fred Dretske, Robert Nozick and others have made a powerful case for rejecting any such principle, however qualified. They attack the closure principle on the basis of a distinctive analysis of knowledge -- what Nozick calls the tracking theory. To know *p* is to track the fact that *p*; simplifying greatly, the claim is that *S* tracks (and hence knows) *p* if and only if there is a reason *R* such that (a) *S*'s belief *p* is based on the fact that R holds, and (b) if *p* were false, *R* would not hold. Somewhat surprisingly, it turns out that we can track a fact, believe a second fact by seeing, correctly, that it follows from the first, yet fail to track the second fact. The main reason is that the following inference is invalid:

1. If *p* were false then *R* would not hold (i.e., we track *p*)

2. *p* entails *q*.

3. So if *q* were false then *R* would not hold (i.e., we track *q*).

Consider one of Dretske's own illustrations: suppose you are in an ordinary zoo standing in front of a cage marked 'zebra'. There is, in fact, a zebra there, in plain sight, and you believe *z*: the animal in the cage in front of you is a zebra. You believe *z* on the basis of *R*, your having zebra-like sensory impressions. You track the fact that *z*; if the animal were not a zebra, you would have different sensory impressions -- *R* would not hold. But now notice that *z* entails *not-m*: the animal in the cage is not a mule that is cleverly disguised to look like a zebra. Seeing this, you believe *not-m*. Your basis for believing *not-m* is your having zebra-like sensory impressions, together with the recognition that these support the belief *z* and that *not-m* follows from *z*. Nonetheless, you fail to track the fact that *not-m*, for if the animal were a cleverly disguised mule, you would still have zebra impressions, leading you to believe *z* and ultimately *not-m*.

As Dretske and Nozick point out, we will probably reject the closure principle if we equate knowledge with tracking. However, many theorists prefer to argue in the other direction: they have assumed, somewhat in the style of G. E. Moore (1959), that the closure principle, suitably qualified, is obviously true, so any argument to the contrary must be flawed. Hence it is the tracking account that must be rejected.

1.2 Indication, Safety, and Closure

Sosa (1999, 2001) and Luper (1984, 1987b) sustain the closure principle by replacing (b) of the tracking account with its contraposition -- namely, *R* would hold only if *p* were true. When this condition is met, *S*'s belief *p* has a property that Sosa calls *safety*; alternatively, one might say that *R indicates* that *p* is true. Suppose that *S* knows *p* if and only if *S* bases the belief *p* on a reason *R* that indicates that *p* is true. Then knowledge is closed, since *R* indicates that a proposition *p* is true only if *R* also indicates that *p*'s consequences are true. For the following inference (via strengthening the consequent) is valid:

1. *R* would hold only if *p* were true (i.e., *R* indicates *p*)

2. *p* entails *q*

3. So *R* would hold only if *q* were true (i.e., *R* indicates *q*).

1.3 Reliabilism and Closure

According to the reliabilist theory of knowledge, *S* knows *p* if and only if *S*'s true belief *p* is caused or sustained by a reliable belief-formation mechanism. Is the reliabilist committed to closure? The answer depends on precisely how the relevant notion of reliability is understood. One of the first reliabilist theories, offered by Alvin Goldman, is very similar to the tracking view, for Goldman argued that knowing *p* entails having the capacity to discriminate between the situation in which *p* is true, on the one hand, and alternative situations (in which *p* is false) that might arise given the circumstances at hand. If we understand reliability as tracking theorists do, we will reject closure. But there are other versions of reliabilism, which sustain closure. For example, the indicator account is a type of reliabilism. Also, we could say that a true belief *p* is reliably formed if and only if based on an event that *usually* would occur only if *p* (or a *p*-type belief) were true. Any event that, in this sense, reliably indicates that *p* is true will also reliably indicate that *p*'s consequences are true.

1.4 Internalism and Closure

Reliabilists adopt externalist accounts of knowledge: they say that factors outside of a subject's perspective can help determine whether she knows things. Other theorists embrace internalism: the view that only factors internal to a subject's perspective can affect the epistemic status of her beliefs. Will internalists accept the principle of closure? The answer is not obvious, since there is no agreed-upon internalist account of knowledge. However, almost all internalists will agree that knowledge entails justified true belief. (Some externalists will accept this too, usually after giving justification an externalist analysis, say in terms of reliable indication.) Assuming they are correct, then the issue of closure rests on whether or not justification is itself closed under entailment. Is it? The matter is not settled. Some argue that justification is not closed, using counterexamples like Dretske's own zebra case: because the zebra is in plain sight, you seem fully justified in believing *z*, but it is not so clear that you are justified in

believing *not-m*, even if you deduce this belief from *z*. Your zebra-like experiences constitute good evidence for *z*, but are they good evidence for *not-m*? The following principle seems questionable:

> If *E* is evidence for *p*, and *p* entails *q*, then *E* is evidence for *q*.

But even if we reject this principle (of the transmissibility of evidence or justification), it does not follow that justification is not closed under entailment, as Peter Klein pointed out. For closure of justification, all that is necessary is that when, given all of our relevant evidence *E*, we are justified in believing *p*, we also have sufficient justification for *p*'s consequences. Our justification for *p*'s consequences need not be *E*. Instead, it might be *p* itself, which is, after all, a justified belief. And since *p* entails its consequences, it is sufficient to justify them. Moreover, any good evidence we have against a consequence of *p* counts against *p* itself, preventing us from being justified in believing *p* in the first place, so if we are justified in believing *p*, considering all our evidence, pro and con, we will not have overwhelming evidence against propositions entailed by *p*. (A similar move could be defended against the tracking theorists when they deny the closure of knowledge: if we track *p*, and believe *q* by deducing it from *p*, then we track *q* if we take *p* as our basis for believing *q*.) Looked at in this way, the following principle of closure of justification seems correct:

> If, considering all of *S*'s evidence, *S* is justified in believing *p*, and *S* believes *q* by deducing it from *p*, then *S* is justified (on the basis of *p*, or alternatively, on the basis of *p* plus the deduction itself) in believing *q*.

However, to avoid paradox, it must be understood that our principle applies only to the implications of individual propositions, not to conjunctions of propositions. We are not always justified in believing the conjunction of claims that are individually justified. To see why, notice that if the chances of winning a lottery are sufficiently remote, then I am justified in believing that ticket 1 will lose. I am also justified in believing that ticket 2 will lose, and that 3 will lose, and so on. However, I am not justified in believing the conjunction of these propositions. If I were, I would justifiably believe that no ticket will win. Yet I know that some ticket will.

2. Is Denying Closure the Key to Resolving the Issue of Skepticism?

According to tracking theorists, we can account for the appeal of skepticism and explain where it goes wrong if we accept their view of knowledge and reject the principle of closure of knowledge. Rejecting closure is therefore the key to resolving skepticism. Given the importance of insight into the problem of skepticism, they would seem to have a good case for denying closure. Let us consider the story they present, and some worries about its acceptability.

2.1 Tracking and Skepticism

According to tracking theorists, skepticism is appealing because skeptics are partially right. They are correct when they say that we do not know that skeptical hypotheses fail to hold. For example, I do not know *not-biv*: I am not a brain in a vat on a planet far from earth being deceiving by alien scientists. For I do not track *not-biv*: if *biv* were true, I would still have the experiences that lead me to believe that *biv* is false. Skeptics are also correct when they point out that *not-biv* is entailed by all sorts of commonsense claims, such as *h*: I am in San Antonio. Having gotten this far, skeptics appeal to the principle of closure, and argue that since I would know *not-biv* if I knew *h*, then I must not know *h* after all. But this is precisely where skeptics go wrong: having accepted the tracking view -- as they do when they deny that we know skeptical hypotheses are false -- skeptics cannot appeal to the principle of closure, which is false on the tracking theory. We track (hence know) the truth of ordinary knowledge claims yet fail to track (or know) the truth of things that follow, such as that incompatible skeptical hypotheses are false.

One problem with this story is that it cannot come to terms with all types of skepticism. There are two main forms of skepticism (and various sub-categories): regress (or Pyrrhonian) skepticism, and indiscernability (or Cartesian) skepticism. At best, Dretske and Nozick have provided a way of dealing with indiscernability skepticism, not regress skepticism.

Another worry about the tracking theorist's account of indiscernability skepticism is that it forces us to give up the principle of closure. Given the intuitive appeal of this principle, some theorists have looked for alternative ways of explaining skepticism. Consider two possibilities, one offered by advocates of the indicator theory and one by contextualists.

2.2 Indication and Skepticism

Advocates of the indicator theory (Sosa 1999, Luper 1987b, 2001) accept the gist of the tracking theorist explanation of the appeal of skepticism but retain the principle of closure. The reason skepticism tempts us is that we tend to confuse the tracking account with the indicator account. After all, the tracking condition -- if *p* were false, *R* would not hold -- closely resembles the indication condition -- *R* would hold only if *p* were true. When we run the two together, we sometimes apply the tracking account and conclude that we do not know that skeptical scenarios do not hold. Then we shift back to the indicator account, and go along with skeptics when they appeal to the principle of entailment, which is sustained by the indicator account, and conclude that ordinary knowledge claims are false. But skeptics are wrong when they say we do not know that skeptical hypotheses are false. Roughly, we know skeptical possibilities do not hold since (given our circumstances) they are remote.

2.3 Contextualism and Skepticism

Contextualists, such as Stewart Cohen (1988, 1999), Keith DeRose (1995) and David Lewis (1996), offer yet another way of explaining skepticism without denying closure. According to contextualists, whether it is correct for a judge to attribute knowledge to someone depends on that judge's context, and the standards for knowledge differ from context to context. When the man on the street judges knowledge, the applicable standards are relatively modest. But an epistemologist takes all sorts of possibilities

seriously that are ignored by ordinary folk, and so must apply quite stringent standards in order to reach correct assessments. What passes for knowledge in ordinary contexts does not qualify for knowledge in contexts where heightened criteria apply. Skepticism is explained by the fact that the contextual variation of epistemic standards is easily overlooked. Skeptics note that in the epistemic context it is inappropriate to grant anyone knowledge. However, skeptics assume -- falsely -- that what goes in the epistemic context goes in all contexts. They assume that since those who take skepticism seriously must deny anyone knowledge, then everyone, regardless of context, should deny anyone knowledge. Yet people in ordinary contexts are perfectly correct in claiming that they know all sorts of things.

Furthermore, the closure principle is correct, contextualists say, so long as it is understood to operate within given contexts, not across contexts. That is, so long as we stay within a given context, we know the things we deduce from other things we know. But if I am in an ordinary context, knowing I am in San Antonio, I cannot come to know, via deduction, that I am not a brain in a vat on a distant planet, since the moment I take that skeptical possibility seriously, I transform my context into one in which heightened epistemic standards apply. When I take the vat possibility seriously, I must wield demanding standards that rule out my knowing I am not a brain in a vat. By the same token, these standards preclude my knowing I am in San Antonio. Thinking seriously about knowledge undermines our knowledge.

Antonio Rosmini

Antonio Rosmini (1797-1855), Italian priest, philosopher, theologian and patriot, and founder of a religious congregation, aimed principally in his philosophical work at re-addressing the balance between reason and religion which had largely been lost as a result of the Enlightenment. To this purpose, he absorbed the tradition of *philosophia perennis*, read extensively the works of post-Renaissance philosophers, and developed his own views on philosophical fundamentals and many of their applications. Best known in Italy, but a controversial figure there during his life and for a century or more after his death, his philosophical work, centred upon the notion of being and the dignity of the human person, can be summarised under the headings: aims and method, the objectivity of thought and the concept of certainty; the dignity of the human person; morality; human rights; the nature of human society; natural theology; and being. The following article will examine Rosmini's work under these titles, which are of perennial relevance and broad enough to embrace more particular themes, such as art, politics, education and marriage, which form a constant preoccupation of many of his lesser works, but can only be mentioned in passing here. His theological principles, other than those pertaining to natural theology, are considered only in so far as they throw light on the origin and development of his philosophical tenets.

1. Life and Works

Rosmini was born in 1797 at Rovereto, Italy, a staunchly Italian-speaking town, but at the time part of the Austro-Hungarian Empire and ruled from Vienna. The Rosmini family, citizens of Rovereto for several centuries, had become rich through the manufacture of silk, and enjoyed the way of life proper to the lesser aristocracy. Antonio's primary and secondary education was, however, catered for at the public school, and through his own intensive reading. Tertiary education was completed at the University of Padua. After ordination to the priesthood in 1821, Rosmini studied and wrote at Rovereto until 1826, and from 1826-28 at Milan. Despite his instinctive distaste for the excesses of the French Revolution, which inevitably played a large part in the cultural formation of persons growing to maturity in the first quarter of the 19th century, Rosmini was not afraid to take a stand against State interference in religious affairs. His *Panegyric for Pius VII* (1823) was considerably censored by the Austrian-Hungarian government and published only in 1831. By this time, Rosmini had founded his religious order (1828), and published at Rome his fundamental philosophical work, *A New Essay concerning the Origin of Ideas* (1830). As the title suggests, this was intended to supersede Locke's famous *Essay concerning Human Understanding*. From then on, a torrent of philosophical and theological works poured out until his death at Stresa. From 1836 until 1855, Rosmini was involved in constant controversy. The approbation of his religious order (1836-38), his work on conscience (1840), theological disputes (1843-48) and his participation in the political events of 1848, occasioned strong debate which led in 1849 to the inclusion of two of his works, *The Five Wounds of Holy Church* and the *Civil Constitution according to Social Justice*, in the *Index of Prohibited Books*. Strengthened by this, Rosmini's theological and political opponents pressed for an examination of all his works which led, however, to his exoneration (1854), a year before his death at Stresa in northern Italy (1855). Condemnation came posthumously (1888-9) when forty propositions, taken mostly from books published after his death, were included in the decree *Post Obitum* of Leo XIII. A remarkable swing in ecclesiastical opinion took place in 2001 when a Vatican *Note* stated: 'The motives for preoccupation and for doctrinal and prudential difficulties which determined the promulgation of the decree *Post Obitum* condemning the "Forty Propositions" drawn from the works of Antonio Rosmini can now be considered as surmounted.' (CDF, *Osservatore Romano*, 1 July 2001)

2. Aim and Method

Rosmini describes his aim and method at some length in his *On the Studies of the Author*. He sets out to combat error, to systematise the truth, to present a philosophy that can serve as a basis for the various branches of knowledge, and to offer philosophy as an aid to theology. To achieve this, he upholds freedom to philosophise, and sets out to reconcile, whenever possible, apparently contrasting views. His intention throughout is to present an image of knowledge as one, simple and indivisible.

Combating error

No one, he maintains, would err for the sake of erring. Philosophical tradition in particular provides an object lesson in the movement towards truth, and the elimination of error. Nevertheless, the path forward is not pursued without error because the movement towards higher levels of reflection takes place unevenly. Responses to questions at level A are no longer adequate in form to resolve questions at level

B, which inevitably take on new aspects through their application to new circumstances. The role of the philosopher is to distinguish the form of difficulties, which may vary from age to age or generation to generation, and to formulate questions in such a way that it is possible to see both their historical antecedents and the underlying principles to be employed in solving them. The process, however, will never be complete. The same principles will always cry out for application to new cases, and the same struggle to avoid error will ensue.

Systematising the truth

The negative task of combating error is not, however, sufficient. What is needed in addition, says Rosmini, is a 'system of truth', that is, a system which shows clearly how the passage is made from the most general, self-evident principles to more particular levels of knowledge. Knowledge-wise, we move instinctively from the more general to the particular. A mother does not begin by naming roses, carnation and other species for her children; she first indicates them all as 'flowers' before calling them by their particular names. So 'being', which is the most general of all notions, is the fundamental principle of human knowledge which draws together every aspect of being. When 'being' is seen as the supreme principle of unity on which all knowledge depends, truth -- 'being as known' -- has been systematised and is seen in all its beauty. Since, however, the full application of being is never seen once and for all, it is better to ensure adherence to principle than to grasp at unconnected facts which serve at best as a ragbag of erudition -- better to grasp the principle of the wheel, for example, than to know only a number of its applications.

Philosophy as a basis for the various branches of knowledge

Philosophy as 'the study of the final reasons' is thus central to Rosmini's understanding. For him, the Enlightenment, with its sensistic, subjectivist attitude and devotion to the act of reasoning, rather than to the light of reason, degenerates inevitably into a hotchpotch of negation and ignorance, leading to radical corruption in ethics, and every other branch of philosophical endeavour.

Philosophy as an aid to theology

The fragmentation of philosophy and its consequent separation from theology is, according to Rosmini, a necessary consequence of sensationalist thinking. There can be no place for revealed doctrine to be expounded as true science unless certain truths are already demonstrated, in the logical order at least, by philosophical reason. On the other hand, theology itself often cannot make progress unless it is prepared to turn to philosophy for assistance. The notions of body, of person and of many other matters essential to theology, cannot be adequately expressed in isolation from philosophical teaching. In its turn, according to Rosmini, divine revelation does not cancel, but completes and ennobles reason, especially by drawing its attention to problems such as the relationship between person and nature which would otherwise escape its attention.

Freedom to Philosophise

Error, the antithesis of knowledge, is the only intellectual impediment to free, philosophical thought. From this principle, Rosmini concludes that assent to erroneous prejudices, not assent to prejudice as such, is the principal obstacle to be overcome by philosophers. Their work consists in examining preconceptions and determining their truth in order to provide grounds for rational persuasion about what they know. To maintain, as many do, that the possession of some unproven truth is inimical to philosophical thought is tantamount to requiring nil knowledge in the prospective philosopher. Rather, a person who knows something, but has not yet come to grips with the reasons leading to it, is like a person who knows the answer to a problem, but still has to consider the reason for the answer. In this case, freedom is not constrained. The point at issue, therefore, in the case of religion, is not that Christians, or Buddhists, or Muslims, or any other religious persons, are necessarily hampered by their beliefs, but whether these beliefs are true, and to what extent they are true. It is not sufficient to state simply that only persons who are devoid of any belief are capable of philosophising freely. Rather

> total freedom is a necessary condition of the truth of faith. If faith were considered divine although in conflict with reason, it would impose an impossible obligation and totally inhibit our reasoning activity. We would be unable to give our assent to either reason or faith, and would thus remain deprived of truth (*IP* 39 [All numbers in references to Rosmini's works are to paragraphs, not to pages]).

It is not the case, Rosmini would affirm, that only non-believers have the capacity to enter the world of philosophical enquiry.

Reconciliation of Conclusions

According to Rosmini, eclecticism, especially that upheld by Victor Cousin, is not the way to promote reconciliation between conclusions. Philosophical systems are not brought together as a result of arbitrary choice between what they offer. Each system, if it is truly such, will have a principle from which deductions are made, and will be able to be reconciled, despite accidental differences, with every other system sharing the same principle. On the other hand, systems will not be reconcilable, despite their accidental agreement, if their basic principles differ. In the former case, agreement will be possible by working back to the principle, and setting out once more from there; in the second case, apparent agreement will only be skin-deep. Only shared principles allow for effective reconciliation between systems.

3. The Objectivity of Thought and the Concept of Certainty

Rosmini sets out to establish the nature of thought and certainty in his *A New Essay concerning the*

Origin of Ideas. Faced by the critical philosophy of Kant on the one hand, and by British empiricism on the other, Rosmini reaches back to the pre-Socratics, to Plato and Aristotle, to Augustine, Thomas Aquinas and Bonaventure, in an endeavour to establish the nature of thought and the basis of certainty in human existence. As his guiding principles he takes the following rules:

> In explaining facts connected with the human spirit, we must not make fewer assumptions than are required to explain them... [nor must we] make more assumptions than are needed to explain the facts (*NE*, vol. 1, 26-7).

With this as his methodological foundation, he places Locke, Condillac, Reid and Dugald Stewart among those whose explanation of the fact of thought is deficient; Plato, Aristotle, Leibniz and Kant are listed amongst those whose explanation is in many ways excessive. In other words, he distinguishes between sensationalists who, according to him, cannot explain the origin of ideas, and idealists who posit in their explanation more ideas or forms than are necessary. For him, however, human thought must depend upon the innate idea of being, without which nothing is intelligible. We cannot think of what is not. At the same time, nothing more is needed than the single idea of being, and its possible determinations, brought about through sensation, to explain all intellectual principles and the ramifications of thought.

Objectivity

After observing the fact of thought, Rosmini concludes that its absolute basis, without which nothing is thought and thought is nothing, must be the knowledge of being. Reflection can remove everything from thought, and still leave it embryonically sound provided the mind is granted the idea of being as its governing light. This idea, which possesses the divine attributes of universality, infinity, necessity and possibility, is not God himself but merely the possibility of things. Moreover, it acts in the mind, but without becoming a subjective part of the mind. As intellectual light, it illuminates, but from outside the mind. And it illuminates without revealing its source, as natural light can be seen without our looking at the sun. It is, as Dante would say, ‘the light connecting intellect and truth’ (*Purgatorio* 6: 45) and, as such, is the quasi-form of the intellect and the image of truth. Determinations of this idea, all of which possess in some way the characteristics of being, especially its objectivity, are provided through sensations experienced in the animal part of human existence and illuminated, being-wise, through the innate idea in which they are seen. Of themselves, sensations do not constitute knowledge but, when felt in the human subject, provide the matter of knowledge which determines the idea of being, that is, the form of knowledge. Knowledge consists first in the intuition of being, the universal, and then in a subsequent series of judgments, or direct perceptions, through which knowing subjects affirm the actual existence of what they have experienced sensationally. These direct perceptions cannot err, although reflection upon them, and a subsequent series of judgments, may be the source of error. In a word, Rosmini holds that basic knowledge, consisting of the idea of being and its immediate determinations, provides all that is needed for objective thought. Against idealists, he reduces the formal requirements of thought to the intuition of being; against sensationalists, he maintains the *per se* inadequacy of the senses to provide more than the matter of thought.

Certainty

Objectivity, therefore, is essentially a characteristic of what is known. Certainty, in Rosmini's view, is a characteristic of the person who knows, and can be defined as 'a firm and reasonable persuasion that conforms to the truth' (*NE*, vol. 3, 1044). In other words, we can be certain only of knowledge, not of error, and this because, according to Rosmini, to know and to know the truth is the same thing. The person who does not know the truth, does not know. There is no doubt, of course, that it is possible to be persuaded, and firmly persuaded, of error. But rational persuasion of error arrived at through one's own reasoning is not possible. In this case, either the premiss is wrong, or the argument is erroneous. On the other hand, the persuasion must be firm. Certainty is not achieved without energy directed into persuasion. Certainty requires that we know something to be true, to be what it is, that we are persuaded that it is what we know it to be, and that we have an adequate reason for our persuasion. And precisely because error attempts to alter the being of things, formal error will not be found rooted in the intellect nor in the senses nor in involuntary reflection. It begins with the will, the only human faculty capable of drawing the reason to invent what it does not see, or to deny what it sees. Under pressure from the will, reason will falsely affirm that being is not, or deny that being is.

4. The Dignity of the Human Person

It is already clear from what has been said that Rosmini, in his solution to the basic problem of knowledge, has offered a perspective which places human dignity on a transcendent level. Human beings are made such, he would maintain, by the intuition of being which accompanies them from the first moment of their existence. Through this intuition, they share in the finality of being itself and in some finite way participate in its infinite characteristics. Nevertheless, the subjective element proper to the human being neither can nor should be denied. Indeed, it has to be examined thoroughly if a rational account is to be rendered of the essential unitary make-up of human nature. This examination was carried out initially in Rosmini's *A New Essay concerning the Origin of Ideas* as part of his explanation of what he called 'impure' ideas, that is, ideas which, as perceptive (not simply intellective), require for their origin some sense experience. He pursued the investigation in his *Anthropology as an Aid to Moral Science* and in *Psychology* where in four volumes entitled *The Essence of the Human Soul*, *The Development of the Human Soul*, *Laws of Animality* and *Opinions about the Human Soul*, he observed and discussed at length the animal, as well as the intellectual side of human nature.

The first fact presented by observation on ourselves is the essential distinction in human beings between that which feels and that which is felt. According to Rosmini, these are quite different and unconfusible elements with opposite characteristics. That which feels is an immaterial principle (soul); that which is felt is the term (body) of this principle. Together feeler and felt constitute feeling, the underlying subject of reflection when attention is concentrated on 'myself' and those elements which constitute 'myself'. The chief action of body is to produce an undetermined, shapeless extension which enables that which feels to experience determined sensations of various kinds. This 'fundamental feeling', with its permanent perception of unlimited space, is that in which all other feelings are perceived, and runs parallel, as it were, with the idea of being in which all other ideas are intuited. Reaction to perceived

feelings constitutes vital instinct (relative to the fundamental feeling) and sensuous instinct (relative to the adventitious sensations). All feeling and instinct is *per se* unknown in Rosmini's view, and comes to be known through the formation in the knowing subject of ideas and perceptions which depend upon the illumination provided by the idea of being. Thus, for Rosmini, the human being is a knowing and feeling subject, having within itself a principle which, formed by the light of being, knows and reacts to what it knows through the faculties of intellect and will, and feels and reacts to what it feels through the faculties of sense and instinct. Within the human subject, the will - which reacts to what is known -- is the supreme active principle and as such constitutes 'person' in the individual. The dignity of the human being lies within the will as such, in the first place, and then within the will's choice to second whatever the intellect knows. This is also the foundation of genuine freedom within the human subject. Free to adhere to or reject what is known, human beings cannot be coerced by attempted external pressure or used as a means by others without prejudice to the inviolable truth in which they share innately through their participation in the light of being and which they attain adventitiously through the direct perception that unfolds determined truths to their intellectual gaze.

5. Morality

Rosmini's ethical philosophy springs directly from the analysis summarised in the previous section. For him, 'the human being is a knowing and feeling subject whose will, as supreme principle of activity, provides the basis of the incommunicable individuality that constitutes each real human nature as a person' (*Life*, p. 26). 'Person', as supreme principle, is also the subject of moral activity, and is to be distinguished from all those habits and acts within human beings which take place without the necessary intervention of the person or, at most, effect the person indirectly. For example, a good pianist is not necessarily a good person. Morality deals necessarily with what people do as persons, with what affects themselves as subjects who cannot step aside from the truth they know without violating their adherence to truth. Rosmini deals with ethics, the science of morality, in his *Principles of Ethics* and in *Comparative and Critical History of Systems dealing with the Principle of Morality*. The *History* first offers an overview of systems which throughout history deny morality, or make it impossible, or provide it with a subjective foundation. It then moves on to summarise the objective view expressed by philosophers and developed by Rosmini in *Principles of Ethics* .

Moral Obligation

This view, as stated by Rosmini, depends upon what he sees as a self-evident principle that cannot be denied by any sane person. We are bound, he says, to acknowledge (recognise) what we know for what we know it to be. Granted that knowledge, according to Rosmini, is co-terminus with truth, never with error, it is clear that Rosmini's affirmation depends upon the self-evident need to affirm what one knows. This, in turn, is an act by which the human subject is elevated, at a reflective level, to the level of the truth which, already known in the essential idea of being, is as sublime as being itself. On the other hand, to deny what one knows is equivalent to stepping into non-being, the antithesis of dignity. In more philosophical terms, Rosmini maintains that the principle he enunciates, in which every other moral dictate is implicitly included, may be characterised as follows: it expresses moral essence because it calls

for agreement between the intellective act of the will and the ideal and real entities of things known; it is simple and as such able to be participated by every moral activity; it is evident because it is nothing more than an expression of the principle of contradiction; it is universal because all moral effects, denoted through external actions, depend upon it; it is supreme because it offers no possibility of further investigation; it provides the foundation for the recognition of the human subject as an essentially moral being, that is, one who, through the innate presence of the idea of being and the principle of will, is furnished with the object of morality and essential adherence to it. Finally, Rosmini's distinction between the subject and object of morality opens a way, according to him, between the extremes of ethical theory. On the one hand, the limitation of the human subject provides for the possibility of moral error; on the other, the necessity and immutability of the object, the idea of being, furnish morality with its undeniable sense of obligation. It is a fatal but all too frequent mistake, Rosmini contends, to attribute characteristics proper to the subject (fallibility, error, and so on) to the object, and characteristics of the object (necessity, immutability and so on) to the subject.

Moral Good

A way is now present to describe adequately the nature of moral good as opposed to eudemonological good. That which is good is desirable, but what is desirable may either be desirable in itself, that is, as it stands in the order of being, or simply desirable in so far it is good, or imagined as good, for the individual. Moral good, says Rosmini, is found when the will adheres to what is good according to the order of being; eudemonological or utilitarian good is what is desired as good for the individual, without reference to what is good in itself. Human dignity is preserved only when, through an act of will, individuals adhering in practice to beings as they are in their order, implicitly adhere to the whole of being and to their presence in that order. Immorality, by which entities are appreciated or desired but not in their known order and thus not as they are, implies an essential rebellion against the order of being and thus against being itself. Self-imposed human indignity can go no lower than this.

Conscience

Having dealt with the nature of morality and moral obligation, Rosmini turns his attention to conscience. He himself admits that such a treatise is almost universally neglected by philosophers, and feels himself constrained to justify such a study, which he undertakes with an almost inevitable admixture of religious and theological elements. Nevertheless, it is not difficult to filter the philosophical principles in his work from characteristics proper to the faith he professes. This is especially apparent in his approach to the nature of conscience, an area in which his views first prompted the dissension's between him and some of his co-religionists that would go on until the end of his life. Rosmini defines conscience as a 'speculative judgement that a person makes about the morality of his practical judgement' (*C*19), that is, a judgement by which individuals come to know the moral value of their actions without necessarily acting upon it.

Several consequences can be drawn from this. First, morality in the individual is prior to conscience, and can be present without conscience; second, conscience can be mistaken (it is possible to form a incorrect

notion of the moral value of one's own action); third, it does not follow that conscience, once formed, will give rise to action in the person who forms it; fourth, conscience, if incorrect in its judgement, must as far as possible be reformed. Conscience, therefore, is only an adequate guide to morality when it provides accurate information of the moral state of a subject's past, present or future action. In the light of these affirmations, it is possible to see how Rosmini lays the groundwork for overcoming the dilemma posed by the question: must conscience always be followed? While it is certain that the dictates of conscience can never be morally disregarded, it is equally certain that a deliberately misleading act of conscience cannot morally be followed. Sometimes, therefore, it will be morally imperative to correct conscience, which is always possible through proper reflection on the moral value of the human act posited or about to be posited by the individual. Rosmini goes on to distinguish between problems about conscience and problems connected with the formation of conscience. In fact, conscience, according to him, is not present as long as judgement is suspended about the moral value of an individual's own action. Difficulties at this point are connected with the formation of the judgement, not with the judgement itself.

6. Human Rights

Rosmini's view of 'person', seen as an inviolable end which can never be reduced to the status of 'means', leads spontaneously to what today is seen as paramount in human existence, that is, the question of human rights. These rights are studied at length in *The Philosophy of Right*, a six-volume treatise in the only extant English translation. The general title of the work shows immediately that for Rosmini all rights are founded in a single element called 'right' from which all 'rights' emanate, some innate in human beings, others springing from the determined circumstances of individuals or societies. The treatise can be summed up under three heads: the essence of right, individual rights, social rights.

The Essence of Right

The basis of Rosmini's teaching on human rights is a consequence of his moral theory, of which he gives a careful synthesis in a preface to *The Philosophy of Right*. If each person is morally obliged to recognise in practice what is known for what it is known to be, every other human being will be recognised as essentially on a par with the knowing person, and will have to be acknowledged as such. But because each person is obliged to act in accordance with moral propriety, every person is obliged to respect this obligation in the other on pain of violating the moral law itself. Granted this principle as foundation, and 'right' as a relationship between one person and others by which a person has a claim to what is his own, Rosmini maintains that 'person' is subsistent right. In other words, all rights are founded on that to which persons have a claim in so far as they are acting morally or are at least not acting immorally. Such activity cannot be the object of attack on the part of others without violation of persons as ends. 'Right', as he says, 'is a moral governance or authority to act, or: right is a faculty to do what we please, protected by the moral law which obliges others to respect that faculty' (*ER*, vol. 1, 237).

The essence of right is, therefore, the activity of a person or persons relative to other persons. This

activity, however, can be exercised either by individuals or by persons acting as members of a society.

Rights of individuals

When a person's activity is actuated in a moral way, the object of that activity becomes the person's own, that is, becomes proper to the person in such a way that it cannot be violated without damage to the person in whose ownership it is. Practical experience of this is found in what Rosmini calls 'jural resentment', the injured feeling that occurs on the occasion of violation of some right and gives rise to an instinct for repossession or restitution. Such an experience is obviously not a fact related solely to matter; it is fundamentally a fact of the spirit where alone it can be felt. It is also an indication of the sphere of jural freedom within which a person is and must be left free. More importantly, 'person' does not possess right, but -- because formed by the light of being -- is right itself; does not possess freedom, but is freedom. The divisions of activity give rise to two major kinds of rights in people. If what is possessed is such from the very beginning of existence in a human being (life, for example), the individual possesses innate right(s) which may be called 'natural' (pertaining essentially to human nature) or 'rational' (the rights are what they are and cannot be otherwise). But rights may also be acquired by human beings during the course of life through adventitious activity. When rights have been established in this way, they too are inviolable although there are circumstances, such as lack of use, which dissolve the relationship of ownership and thus leave the field open to others who may wish to extend their activity to the matter in question. Leaving these circumstances aside, however, individual rights cannot be absorbed by others. The State, for example, cannot absorb the inalienable rights proper to persons, nor can it be considered as more than its individual members in such a way that persons can be sacrificed for the sake of society.

Social right

Nevertheless, societies exist within which rights arise from the bonds between intellectual beings. According to Rosmini, these societies fall under three headings: theocratic society, that is, society between God and his creatures; domestic society, which is divided into conjugal and parental society; and civil society, that is, the communion desired by several families who wish to entrust the preservation and the regulation of their rights to a single or collective mind called 'government'. Rosmini considers at some length the rights arising in these societies. In particular, he ponders the title of rights possessed by the Creator over human beings, the rights proper to husband and wife, and to parents. Of special interest is his description of the State as a society which, while it has the duty to influence for the common good only the modality and exercise of rights in its citizens, has no power to create or destroy human rights. In fact, the general purpose of the State is to arrange the exercise of individual rights in such a way that individuals are better able to enjoy the use of their innate and acquired rights. Thus, although in time of war the exercise of certain rights may be curtailed or even suspended, the rights remain invested in individuals to whose exercise they must be restored in normal circumstances. It is clear that Rosmini's view of civil society is completely anti-totalitarian. He does not, however, espouse the cause of modern democracy According to him, the principle of democracy is not 'one person, one vote', but would depend rather upon the contribution made by citizens to the well-being of the State. Difficult to arrange in

practice, the principle is nevertheless important, and can be considered the obverse of ‘No taxation without representation’.

7. The Nature and Purpose of Society

It is clear that Rosmini’s view of rights in human society depends to a great extent on his views about the nature of society as such. In fact, his earliest work as a philosopher (1818-1826) was almost totally taken up with a study of society, and was only abandoned when he saw that his ideas would lack a solid foundation unless the problem of knowledge had first been confronted. Eventually (1837), he published his ideas on society in *The Philosophy of Politics* in which he deals with the principle according to which societies stand or fall, and the end to which societies are directed. . However, despite the universality of the principles examined in this work, their application is restricted to civil society. According to Rosmini, the first rule and criterion for governing any society whatsoever is this: That which constitutes the existence or substance of a society is to be preserved and strengthened even at the cost of neglect to accidental refinement. This is also the first rule of politics. It follows that the greatest errors of government are those by which the government of a society, because of its excessive concern for the society’s accidental progress, loses sight of that which constitutes the substance of the society. The steps taken towards decline, that is, towards the substitution of essential matters by accidental, can be considered on four levels: the periods of founders of societies and basic legislation; of genuine development; of external splendour; of frivolity. Beginning from the first stage, when attention is inevitably fixed on the nature itself of a society, there is a gradual diminution of interest in underlying societal values until weakeness, manifested in attention to frivolities and inability to concentrate on weightier matters, undermines the society’s inner cohesion and its ability to withstand external inimical pressures. This would explain the profound truth lying behind Machiavelli’s observation: ‘If a sect or republic is to survive for any length of time, it must return frequently to its beginning’ (quoted in *PP*, vol. 1, 41)

For Rosmini, every society is simply the union of two or more people undertaken with the intention of obtaining a common advantage. ‘All the persons in this union [forming a society] together have the role of end, and the advantage expected from the association is applied equally to all (*PP*, vol. 2, 39). In other words, there must be in every society a moral element, an element of justice, which affects the behaviour of the members towards one another, even if collectively (as in Plato’s case of a band of robbers) they are unjust towards non-members. Hence the excellence of what Rosmini calls ‘the social bond’; where it is present and actuated, there is no injustice; injustice begins in its absence. In other words, the nature of society requires that those who form it, enjoy within it the personal dignity of end. There is, therefore, a moral element inherent in every society. Using some persons, some members, as means, even for the apparent good of the whole, is repugnant to the very nature of society. In a coherent universal society, such as that described by Cicero -- ‘This entire world is to be considered simply as a city common to both gods and human beings’ (quoted in *PP*, vol. 2, 49) -- there will inevitably be a tendency to maximum justice. This means, however, that no one in any society can make one person subservient to another. All that is pertinent only to nature can be used as means; all that which is proper to person, or to which persons have extended themselves so that some thing or things have become proper to them, must

be respected as end. Here again, though, a distinction must be made between that is proper to a member of a society as a person, and the modality of that which is proper. In certain cases, the government of a society may change the modality of what is proper if this is for the common good. A piece of land required for a road may, for instance, be substituted with an adequate sum of momey. But those things which have no modality, such as innocent life, cannot be violated under the pretext of commmon good. It is clear that these principles must direct the government of every society.

Rosmini also deals with the nature of the good which is the aim or end of society. For him, this good is human good which 'resides in virtue and the eudemenological appurtenances of virtue, and in general in every good in so far as it is connected with virtue.' He concludes, therefore, that every society, in so far as it is contrary to virtue, is illegitimate because its aim is contrary to the essence of society. At the same time, every law of society is invalid if, or in so far as, it prevents members from achieving virtue. 'Without virtue there is no human good, the end for which society is established' (*PP*, vol. 2, 189). But while anti-virtue is essentially detrimental to the good of any society, virtue of itself is not the only element forming the good in question. Contentment of spirit, that is, of the whole person, as distinct from passing pleasure confined to parts of human nature, is also included in every society's essential aim. Anything, therefore, opposed to contentment is inevitably detrimental to society, whatever favour it may have found in public opinion. Rosmini finds support for this affirmation in Hamilton, whom he quotes approvingly (*PP*, vol. 2, 195).

> When occasions present themselves in which the interests of the people are at variance with their inclinations, it is the duty of the persons whom they have appointed to be the guardians of those interests to withstand the temporary delusion in order to give them time and opportunity for more cool and sedate reflection.

Public opinion, it would seem, is not an infallible criterion of public good.

8. Natural theology

Rosmini's natural theology, in the conventional philosophical sense of natural theology, can be summarised under two headings: proofs for the existence of God, found scattered throughout his philosophical writings, and theodicy, developed at length in a work of that name. But it will also be considered, under the heading 'Being' according to the meaning given it by Rosmini.

The existence of God

In his natural theology, Rosmini offers considerations which are consistent with the basic principles of his philosophical teaching. Although he does not deny the validity of *a posteriori* proofs of the existence of God, he affirms that an *a priori* method is more satisfactory because it sets off from the idea of being, the foundation of his philosophy, and argues to the necessity of God's existence. First, however, he posits a fundamental barrier to the perception of God at a purely natural level of human nature. For Rosmini,

what is real can only be perceived through feeling, which indeed is part of human existence but only at a finite level where it cannot be the vehicle of the perception of God’s infinite reality. Ideal being, however, while expressing only the possibility, not the reality of things, is shown on analysis to be characterised by necessity, eternity and immateriality, factors which are intrinsic marks of possibility. The idea of being, therefore, with its divine characteristics serves as a bridge between God and human beings, enabling us to posit proofs of God’s existence without our knowing him through perception, or real contact. One example of the *a priori* proofs may be given here. If infinite, intelligible being is present to the human mind -- and Rosmini would maintain that it is -- an infinite mind capable of giving this idea to humans must exist. But such a mind cannot not be God. In this and all similar proofs, there is a common mode of procedure. The existence of God is necessary for the existence of intelligible being; but intelligible being certainly exists; the existence of God is therefore necessary. Having determined the existence of God, Rosmini then makes use of divinely revealed truth as a basis on which to offer some reflections about the nature of what he has proved to exist. These reflections, he would maintain, lie within the scope of philosophy because they depend methodologically solely on reason, and conclude with rational, not authoritative affirmations. Their basis in revelation, however, precludes any examination of them here.

Theodicy

Rosmini provides an exact description of his aim in his work on theodicy. ‘Theodicy (theou dike) means "justice of God". The intent of this work, therefore, is simply this: to justify God’s equity and goodness in the distribution of good and evil in the world.’ (*Theodicy* preface).

He also provides a clear indication of the method he will follow in the three books composing his *Theodicy*. The first prescribes the norms to be followed in judging about the disposition of divine providence if error is to be avoided; the second considers the laws of nature, the necessary limitations of what is created and the chain of causes operating in the universe; the third is devoted to the laws according to which God’s action takes place in the world he has created. These laws all spring from a single norm, the law of the least means, which Rosmini, following Aquinas, posits as follows: ‘The wise worker carries out his work in the briefest way possible’ (*Sapiens operator perficit opus suum breviori via qua potest*. *ST*, III, q. 4, art. 5, ad 3um). From this law, another ten are deduced whose titles provide a useful indication of their possible application. They are the laws of: excluded superfluity, the permission of evil, excluded equality, unity in the divine work, heroism, antagonism, rapidity in work, accumulation of good, and germ. These laws, according to Rosmini, are concerned with God’s providence relative to universal good. At the same time, but relative to particular good, the law followed is that of: supreme justice, equity, fittingness and conformity to God’s divine attributes. Divine governance consists in acting in such a way that the aspects of universal and particular good are harmonised.

9. Being

The last nine years of Rosmini’s life, with the exception of 1848-9 when he was actively engaged in

political affairs, were spent in great part working on his *Theosophy* (*Teosofia*). Despite its size (five volumes), this monumental work remained unfinished at Rosmini's death and was published posthumously. The title itself, despite its obvious etymological implications, is today unhelpful. It would seem to indicate a philosophy 'professing to achieve a knowledge of God by spiritual ecstasy, direct intuition or special individual relations' (*COD*). Rosmini, however, is concerned here only with reasoning about God, and takes the word 'theosophy' in its fundamental meaning of 'wisdom about God' in so far as God is the supreme Being and the apex of philosophical speculation. Such speculation must sooner or later deal with the problem of the One Being and many beings, with unity and plurality in all their manifestations. In many ways, the book is a direct challenge to Hegel and Schelling with whose philosophy Rosmini had become thoroughly familiar as a result of the great editions of their works published in the 1830s and early 1840s. Kant's teaching, already challenged in Rosmini's *A New Essay concerning the Origin of Ideas*, was now to be opposed in what Rosmini perceived as the delirium and exaggerations of Kant's Idealist successors.

> Whenever we try to reduce the whole human being to speculation, and substitute the part for the whole, we presume that all human good must lie solely in speculation. As result, we make every effort to turn what is real into an idea; we try to derive from the idea the matter which constitutes the sensible world, together with the Spirit and finally God himself… But although Schelling and Hegel claimed that they had reached such total science, they still needed to teach it publicly not only for the sake of attaining the practice of virtue (which would make it worthwhile), but even to draw a salary. This proves without doubt that their absolute idea did not contain everything. If the world were present in it, as they said it was, wheat, bread and wine would have been there also. My theosophy certainly cannot give the public such magnificent and wonderful promises, but it will explain how the speculative human mind is inclined to find everything in itself. In other words, it will demonstrate that there must be an object which contains effectively within itself the universality of things, and that this object is not the idea in our mind. Nevertheless, the idea which shines in the human mind draws its form as object from that object. Hence, because the idea also is *per se* object, we easily confuse it, in our speculation, with the complete, subsistent object. A strong desire then arises in us of attributing to the idea which we intuit the attributes of the subsistent object which we know must exist, although we do not intuit it. The tendency to unity, an essential element of every intellect, causes this error and forces us towards an abyss of unseen absurdities in the hope that these will satisfy our desperate purpose. We should acknowledge (and this theosophy will demonstrate) that if being itself has an objective existence, it is *per se* intelligible, and that if it contains everything (that which is not being is nothing), everything must also be contained in that which is intelligible. Theosophy will also clearly show that, although being must actually have this primal form, human nature cannot intuit *the intelligible which contains all*. Human nature arrives at this solely by reasoning, which can provide only a formal, negative concept of it. We cannot therefore have either the absolute knowledge which Schelling attributes to us through direct intuition, or the absolute idea which his disciple, George Hegel (who was opposed to all immediacy), promised us by mediate reasoning… (*TH*, vol. 1, Preface, 9-10)

But the main thrust of the work is positive, rather than critical.

> Theosophy will not be wasting time by demonstrating that behind this well-conceived and ingenious error [of Hegel] lies a great truth which those courageous speculative minds [Schelling and Hegel] tried in vain to grasp but could not. This truth is precisely the necessity I spoke of: there must be ‘something intelligible and eternal which contains everything’... Nevertheless, although absolute knowledge is proper to God but not to us, we do have an absolute knowledge relative to form, but not to matter (cf. *NE*, vol. 1, 325, 474-476). This kind of absoluteness of human knowledge caused errors in the German school, which I have already discussed. Theosophy must speak at length about absolute human knowledge, indeed it must use it and more importantly be it. Theosophy is simply the Theory of Ens (this definition is not to be despised, despite its being only two words). Because ens is first of all infinite and absolute, and only later enclosed and existing within limits as finite, no thought could attain it unless thought itself somehow became absolute. A thought informed by an object which is in some way absolute, is itself in some way made absolute. Plato therefore rightly called the treatise on what is greatest, the treatise about ens. There is nothing in the universe or in our mind antecedent to ens or being. When, in the order of things, we remove being, nothing remains except darkness in the order of cognition. For this reason the doctrine of ens, which I call ‘theosophy’, corresponds to the concept of philosophy in the ancients. According to them, philosophy differs from other sciences in that all other sciences suppose undemonstrated principles. Philosophy, however, which borrows nothing from anywhere, uses its own materials to construct itself. It starts from no gratuitous hypothesis or supposition -- on the contrary, it seeks and establishes what is undemonstrable, which gives it an unshakeable basis, and admits only what is necessary (*Ibid*., 10-12).

For Rosmini, the problem of being is finally considered under the three divisions of the science of theosophy: ontology, rational theology and cosmology, each of which must enter into the other if the science is to be complete. In fact, he maintains, it is impossible to speak of being in all its universal essence (ontology), without regard to the infinity and absoluteness of Being (rational theology), just as it is impossible to consider the world philosophically (cosmology) without taking its cause into consideration. Each of the three divisions of theosophy is as essential to the whole as, according to his example, the various vital organs are necessary to the existence of an animal. But the centre and substance of the whole treatise is teaching about God, without which there is no final explanation of the being or the world. Theosophy, therefore, is a single science which, through its division into three parts, is both one and three. Such an affirmation is paradigmatic of the thrust of Rosmini’s theosophy which eventually enables him to confront this rational science with the doctrine of the Trinity.

Ontology

Ontology, according to Rosmini’s description of it, considers being in all its universality, but only as the object of human thought which puts limited, intellectual beings in contact with the possibility of all that

is, not with actuality (it is impossible, for instance, to assuage hunger by thinking about a meal). Thought must, therefore, reach out to absolute reality not through direct perception of God, but by means of concepts. Ontology, dealing with these concepts analytically and synthetically is, as it were, an immense preface to rational theology. Ontology as the theory of being in all its possibility is the necessary propedeutic to theology as the theory of absolute being without which ontology itself is inevitably incomplete, and cannot progress beyond a treatise on categories and on dialectic.

Rational theology

If, as Rosmini suggests, ontology is the ‘theory of abstract being’, rational theology is the ‘theory of subsistent Being’. These two parts of theosophy cannot, however, can be distinguished only if the same universal concepts, of which both are formed, can in some way be differentiated. This is done by considering that ontology serves to find, review, and describe the nature and relationship of these concepts; theology, in Rosmini’s understanding, synthesises them to form a single concept of the infinite Being. It is true that such a concept remains abstract (the essence contained in the concept is not beheld by the knowing subject), but the ‘theologian’ passes from the concept to affirm subsistent Being, which is therefore no longer a mere concept, but something which must exist in itself. An effort is then made in rational theology to see how the ontological concepts have their truth and their foundation in first subsistent Being. While this takes place, the concepts themselves are identified and become one. Their separation, now considered anew, is seen to be relative not to first subsistent Being, but to the beholding, finite mind. The problem of the One and the many is rooted not in the nature of absolute, subsistent Being, but in being by participation.

Cosmology

Ontology, while a preface to rational theology, is also necessary for knowledge of the intimate nature of finite being and the world. Rosmini posits three reasons for this. First, although finite being is perceived, perception is limited to very few beings. If the essential conditions of this being are to be known, it is necessary to know the common conditions of all finite beings. This cannot be done without recourse to universal principles which enable us to deduce what is lacking to limited experience. Second, the same principles are needed to provide a notion of finite beings in themselves, divested of the sensory phenomena that accompany their perception. Third, subsistent Being, if known, would be intelligible *per se*. This is not the case with finite beings, which are known through their participation in intellectual light, and consequently remain unknown without some relationship to concepts.

Affirmative Action

"Affirmative action" means positive steps taken to increase the representation of women and minorities in areas of employment, education, and business from which they have been historically excluded. When those steps involve *preferential* selection -- selection on the basis of race, gender, or ethnicity -- affirmative action generates intense controversy.

The development, defense, and contestation of preferential affirmative action has proceeded in two streams. One has been legal and administrative, as courts, legislatures, and executive departments of government have applied laws and rules requiring affirmative action. The other has been public debate, where the practice of preferential treatment has spawned a vast literature, pro and con. Often enough, the two streams have failed to make adequate contact, with the public quarrels not always very securely anchored in any existing legal basis or practice.

The ebb and flow of public controversy over affirmative action can be pictured as two spikes on a line, the first spike representing a period of passionate debate that began around 1972 and tapered off after 1980, and the second indicating a resurgence of debate in the 1990s. The first spike encompassed controversy about gender and racial preferences alike. This is because in the beginning, affirmative action was as much about the factory, firehouse, and corporate suite as about the university campus. The second spike represents a quarrel about race. This is because the only burning issue now is about preferential admissions in higher education.[1]

1. In the Beginning

In 1972, affirmative action became an inflammatory public issue. True enough, the Civil Rights Act of 1964 had made something called "affirmative action" a remedy federal courts could impose on violators of the Act. Likewise, since 1965, federal contractors had been subject to President Lyndon Johnson's Executive Order 11246, requiring them to take "affirmative action" to make sure they were not discriminating. But what did this 1965 mandate amount to? The Executive Order assigned to the Secretary of Labor the job of specifying rules of implementation. In the meantime, as the federal courts were enforcing the Civil Rights Act against discriminating companies, unions, and other institutions, the Department of Labor mounted an ad hoc attack on the construction industry, cajoling, threatening, negotiating, and generally strong-arming reluctant construction firms into a series of region-wide "plans," in which they committed themselves to numerical hiring goals. Through these contractor commitments, the Department could indirectly pressure recalcitrant labor unions, who supplied the employees at job sites.

While the occasional court case and government initiative made the news and stirred some controversy, affirmative action was pretty far down the list of public excitements until the autumn of 1972, when the Secretary of Labor's Revised Order No. 4, fully implementing the Executive Order, landed on campus by way of directives from the Department of Health, Education, and Welfare. Its predecessor, Order No. 4, first promulgated in 1970, cast a wide net over American institutions, both public and private. By extending to all contractors the basic apparatus of the construction industry "plans," the Order imposed a one-size-fits-all system of "underutilization analyses," "goals," and "timetables" on hospitals, banks, trucking companies, steel mills, printers, aircraft manufacturers -- indeed, on all the scores of thousands of institutions, large and small, that did business with the government -- including a special set of institutions with a particularly voluble and articulate constituency, namely, American universities.

At first, university administrators and faculty found the new rules murky but hardly a threat to the established order. The number of racial and ethnic minorities receiving PhDs each year was tiny. Any mandate to increase their representation on faculties would require more diligent searches by universities, to be sure, but searches nevertheless fated largely to mirror past results. The Revised Order, on the other hand, effected a change that punctured any campus complacency: it included women among the "protected classes" whose "underutilization" demanded the setting of "goals" and "timetables" for their "full utilization."[2] Unlike blacks and Hispanics, women were getting PhDs in substantial and growing numbers. If the affirmative action required of federal contractors was a recipe for "proportional representation," then Revised Order No. 4 was bound to leave a large footprint on campus. Some among the professoriate exploded in a fury of opposition to the new rules, while others responded with an equally vehement defense of them.[3]

As it happened, these events coincided with another development, namely the "public turn" in philosophy. For several decades Anglo-American philosophy had treated moral and political questions obliquely. On the prevailing view, philosophers were competent to do "conceptual analysis" -- to lay bare, for example,

the conceptual architecture of the idea of justice -- but they were not competent to suggest political principles, constitutional arrangements, or social policies that actually did justice. Philosophers might do "meta-ethics" but not "normative ethics." This viewed collapsed in the 1970s under the weight of two counter-blows. First, John Rawls published in 1971 *A Theory of Justice*,[4] an elaborate, elegant, and inspiring defense of a *normative* theory of justice. Second, in the same year *Philosophy & Public Affairs*, with Princeton University's impeccable pedigree, began life, a few months after Florida State's *Social Theory and Practice*. These journals, along with a re-tooled older periodical, *Ethics*, became self-conscious platforms for socially and politically engaged philosophical writing, born out of the feeling that in time of war (the Vietnam War) and social tumult (the Civil Rights Movement, women's liberation), philosophers ought to do, not simply talk about, ethics. In 1973, *Philosophy & Public Affairs* published Thomas Nagel's "Equal Treatment and Compensatory Justice"[5] and Judith Jarvis Thomson's "Preferential Hiring,"[6] and the philosophical literature on affirmative action burgeoned forth.[7]

In contention was the nature of those "goals" and "timetables" imposed on every contractor by Revised Order No. 4. Weren't the "goals" tantamount to "quotas," requiring institutions to use racial or gender preferences in their selection processes? Some answered "no."[8] Properly understood, affirmative action did not require (or even permit) the use of gender or racial preferences. Others said "yes."[9] Affirmative action, if it did not impose preferences outright, at least countenanced them. Among the yea-sayers, opinion divided between those who said preferences were morally indefensible and those who said they were not. Within this last set, different people put forward different justifications.

2. The Controversy Engaged

The essays by Thomson and Nagel both defended the use of preferences but on different grounds. Thomson defended job preferences for women and blacks as a form of compensation for their past exclusion from the academy and the workplace. Preferential policies, in her view, worked a kind of justice. Nagel, by contrast, thought that preferences might work a kind of social good, and without doing violence to justice. Institutions could for one or another good reason properly depart from standard meritocratic selection criteria because the whole system of tying economic reward to earned credentials was itself indefensible.

Justice and desert lay at the heart of subsequent arguments. Several writers took to task Thomson's argument that preferential hiring justifiably makes up for past wrongs. Preferential hiring seen as compensation looks perverse, they contended, since it benefits individuals (blacks and women possessing good educational credentials) least likely harmed by past wrongs while it burdens individuals (younger white male applicants) least likely to be responsible for past wrongs.[10] Instead of doing justice, preferential treatment violates rights (the right of an applicant "to equal consideration,"[11] the right of the maximally competent to a position,[12] the right of everyone to equal opportunity[13]) and confounds desert (by severing reward from a "person's character, talents, choices and abilities;"[14] by "subordinating merit, conduct, and character to race;"[15] by disconnecting outcomes from actual liability and damage[16]).

Defenders of preferences were no less quick to enlist justice and desert in their cause. Mary Anne Warren, for example, argued that in a context of entrenched gender discrimination, gender preferences might improve the "overall fairness" of job selections. Justice and individual desert need not be violated.

> If individual men's careers are temporarily set back because of . . . [job preferences given to women], the odds are good that these same men will have benefited in the past and/or will benefit in the future -- not necessarily in the job competition, but in some ways -- from sexist discrimination against women. Conversely, if individual women receive apparently unearned bonuses [through preferential selection], it is highly likely that these same women will have suffered in the past and/or will suffer in the future from . . . sexist attitudes.[17]

Likewise, James Rachels defended racial preferences as devices to neutralize unearned advantages by whites. Given the pervasiveness of racial discrimination, it is likely, he argued, that the superior credentials offered by white applicants do not reflect their greater effort, desert, or even ability. Rather, the credentials reflect their mere luck at being born white. "Some white . . . [applicants] have better qualifications . . . only because they have not had to contend with the obstacles faced by their black competitors."[18] Rachels was less confident than Warren that preferences worked uniformly accurate offsets. Reverse discrimination might do injustice to some whites; yet its absence would result in injustices to blacks who have been unfairly handicapped by their lesser advantages.

Rachels' diffidence was warranted in light of the counter-responses. If racial and gender preferences for jobs (or college admissions) were supposed to neutralize unfair competitive advantages, they needed to be calibrated to fit the variety of backgrounds aspirants brought to any competition for these goods. Simply giving blanket preferences to blacks or women seemed a much too ham-handed approach if the point was to micro-distribute opportunities fairly.[19]

3. Rights and Consistency

To many of its critics, reverse discrimination was simply incoherent. When "the employers and the schools *favor* women and blacks," objected Lisa Newton, they commit the same injustice perpetrated by Jim Crow discrimination. "Just as the previous discrimination did, this reverse discrimination violates the public equality which defines citizenship."[20]

William Bennett and Terry Eastland likewise saw racial preferences as in some sense illogical:

> To count by race, to use the means of numerical equality to achieve the end of moral equality, is counterproductive, for to count by race is to deny the end by virtue of the means. The means of race counting will not, cannot, issue in an end where race does not matter.[21]

When Eastland and Bennett alluded to those who favored using race to get to a point where race doesn't

count, they had in mind specifically the Supreme Court's Justice Blackmun who, in the famous 1978 *Bakke* case (discussed below), put his own views in just those simple terms. The legitimacy of racial preferences was to be measured by how fast using them moved us toward a society where race doesn't matter (a view developed in subtle detail by the philosopher Richard Wasserstrom).[22] While the critics of preferences feigned to find the very idea of using race to end racism illogical and incoherent, they also fell back on principle to block this instrumental defense should it actually prove both reasonable and plausible. "The moral issue comes in classic form," wrote Carl Cohen. "Terribly important objectives . . . appear to require impermissible means. Might we not wink at the Constitution this once" and allow preferences to do their good work?[23] Neither Cohen nor the other critics thought so. Principle must hold firm. "[I]n the distribution of benefits under the laws *all* racial classifications are invidious."[24]

But what, exactly, *is* the principle -- Constitutional or moral -- that bars the use of race as a means to "terribly important objectives"? Alan Goldman did more than anyone in the early debate to formulate and ground a relevant principle. Using a contractualist framework, he surmised that rational contractors would choose a rule of justice requiring positions to be awarded by competence. They would choose this rule because it instantiates a principle of equal opportunity which in turn instantiates a broad right to equal consideration of interests, this last principle springing from the basic condition of the contracting parties as rational, self-interested, and equally situated choosers. On its face, the rule of competence would seem to preclude filling positions by reference to factors like race and gender that are unrelated to competence. However, Goldman's "rule" blocked preferences only under certain empirical conditions. Goldman explained the derivation of the rule and its consequent limit this way:

> The rule for hiring the most competent was justified as part of a right to equal opportunity to succeed through socially productive effort, and on grounds of increased welfare for all members of society. Since it is justified in relation to a right to equal opportunity, and since the application of the rule may simply compound injustices when opportunities are unequal elsewhere in the system, the creation of more equal opportunities takes precedence when in conflict with the rule for awarding positions. Thus short-run violations of the rule are justified to create a more just distribution of benefits by applying the rule itself in future years.[25]

In other words, if "terribly important objectives" -- especially objectives having to do with equalizing opportunities in a system rife with inequality -- could in fact be furthered by measured and targeted reverse discrimination, justice wouldn't stand in the way. Thus, Goldman's rule did not have the adamantine character Cohen and other critics sought in a bar to preferences. Where can such an unyielding principle be found? I postpone further examination of this question until I discuss the *Bakke* case, below, whose split opinions constitute an extended debate on the meaning of Constitutional equality.

4. Real-World Affirmative Action -- The Workplace

The terms of the popular debate over racial and gender preferences mirrored the arguments philosophers and other academics were making to each other. Preference's defenders offered many reasons to justify

them, reasons having to do with compensatory or distributive justice, as well as reasons having to do with social utility (more blacks in the police department would enable it better to serve the community, more female professors in the classroom would inspire young women to greater achievements). Critics of preferences retorted by pointing to the law. And well they should, since the text of the Civil Rights Act of 1964 seemed a solid anchor even if general principle proved elusive. Title VI of the Act promised that "[n]o person . . . shall, on the ground of race, color, or national origin, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance."[26] Title VII prohibited all employment practices that discriminated on the basis of race, gender, religion, or national origin.[27] However, unlike Title VI, Title VII went on to spell out some exceptions. Under special circumstances, the Title permitted the use of gender, religion, and national origin as legitimate bases for employer selection. But it made no such exception for race. While being a woman or being a Roman Catholic could sometimes count as a legitimate occupational qualification, being black could not.

In face of the plain language of Titles VI and VII, how did preferential hiring and promotion ever arise in the first place? How could it be justified legally? The answer lay in the meaning of "discrimination." The Civil Rights Act did not define the term. The federal courts had to do that job themselves, and the cases before them drove the definition in a particular direction. Many factories and businesses prior to 1964, especially in the South, had in place facially discriminatory policies and rules. For example, a company's policy might have relegated blacks to the maintenance department and channeled whites into operations, sales, and management departments, where the pay and opportunities for advancement were far better. After passage of the Civil Rights Act, suppose the company willingly abandoned its facially segregative policy. Yet it could still carry forward the effects of its past segregation through other already-existing facially neutral rules. For example, a rule requiring workers to give up their seniority in one department if they transferred to another would have locked in place older black maintenance workers as effectively as the prior segregative rule that made them ineligible to transfer at all. Consequently, courts began striking down facially neutral rules that carried through the effects of an employer's past discrimination, regardless of the original intent or provenance of the rules. "Intent" was effectively decoupled from "discrimination." In 1971, the Supreme Court ratified this process, giving in the *Griggs* decision the following construction of Title VII:

> The objective of Congress in the enactment of Title VII . . . was to achieve equality of employment opportunities and remove barriers that have operated in the past to favor an identifiable group of white employees over other employees. Under the Act, practices, procedures, or tests neutral on their face, and even neutral in terms of intent, cannot be maintained if they operate to "freeze" the status quo of prior discriminatory employment practices.
>
> ...
>
> What is required by Congress is the removal of artificial, arbitrary, and unnecessary barriers to employment when the barriers operate invidiously to exclude on the basis of racial or other impermissible classification.[28]

In a few short paragraphs the Court moved from proscribing practices that froze in place the effects of a firm's own past discrimination to proscribing practices that carried through the effects of past discrimination generally. The Court characterized statutory discrimination as *any exclusionary practice not necessary to an institution's activities*. Since many practices in most institutions were likely to be exclusionary, rejecting minorities and women in greater proportion than white men, all institutions needed to reassess the full range of their practices to look for, and correct, discriminatory effect. Against this backdrop, the generic idea of affirmative action took form:

> Each institution should effectively monitor its practices for exclusionary effect and revise those that cannot be defended as "necessary" to doing business. In order to make its monitoring and revising effective, an institution ought to predict, as best it can, how many minorities and women it would select over time, were it successfully nondiscriminating. These predictions constitute the institution's affirmative action "goals," and failure to meet the goals signals to the institution (and to the government) that it needs to revisit its efforts at eliminating exclusionary practices. There may still remain practices that ought to be modified or eliminated.[29]

The point of such affirmative action: induce change in institutions so that they could comply with the nondiscrimination mandate of the Civil Rights Act.

However, what if this self-monitoring and revising fell short? In early litigation under the Civil Rights Act, courts concluded that some institutions, because of their past exclusionary histories and present failure to find qualified women or minorities, needed stronger medicine. Courts ordered these institutions to adopt "quotas," to take in specific numbers of formerly excluded groups, on the assumption that once these new workers were securely lodged in place, the institutions would adapt to this new reality.[30]

Throughout the 1970s, courts and government enforcement agencies extended this idea across the board, requiring a wide range of firms and organizations -- from AT&T to the Alabama Highway Patrol -- temporarily to select by the numbers. In all these cases, the use of preferences was tied to a single purpose: to prevent ongoing and future discrimination. Courts carved out this justification for preferences not through caprice but through necessity. They found themselves confronted with a practical dilemma that Congress had never envisaged and thus never addressed when it wrote the Act. The dilemma was this: courts could impose racial preferences to change foot-dragging or inept defendants (thus transgressing the text of Title VII) or they could order less onerous steps they knew to be ineffective, thus letting discrimination continue (and violating their duty under Title VII). Reasonably enough, the federal courts resolved this dilemma by appeal to the broad purposes of the Civil Rights Act and justified racial preferences where needed to prevent ongoing and future discrimination.[31]

Thus, preferential affirmative action served the same rationale as the non-preferential sort. Its purpose was *not* to compensate for past wrongs, offset unfair advantage, appropriately reward the deserving and undeserving, or yield a variety of social goods; its purpose was to change institutions so they could

comply with the nondiscrimination mandate of the Civil Rights Act.

5. Real-World Affirmative Action -- The University

In the 1970s, while campuses were embroiled in debate about how to increase blacks and women on the faculty, universities were also putting into effect schemes to increase minority presence within the student body. Very selective universities, in particular, needed new initiatives because only a relative handful of black and Hispanic high school students possessed test scores and grades good enough to make them eligible for admission. These institutions faced a choice: retain their admissions criteria unchanged and accept the upshot -- hardly any blacks and Hispanics on campus -- or fiddle with their criteria to get a more substantial representation. Most elected the second path.

The Medical School of the University of California at Davis was typical. It reserved sixteen of the one hundred slots in its entering classes for minorities. In 1973 and again in 1974, Allan Bakke, a white applicant, was denied admission although his test scores and grades were better than most or all of those admitted through the special program. He sued. In 1977, his case, *Regents of the University of California v. Bakke*, reached the Supreme Court. The Court rendered its decision a year later.[32]

An attentive reader of Title VI of the Civil Rights Act might have thought this case was an easy call. So, too, thought four justices on the Supreme Court, who voted to order Bakke admitted to the Medical School. Led by Justice Stevens, they saw the racially segregated, two-track scheme at the Medical School, which was a recipient of federal funds, as a clear violation of the plain language of the Title.

Four other members of the Court, led by Justice Brennan, wanted very keenly to save the Medical School program. To find a more attractive terrain for doing battle, they made an end-run around Title VI, arguing that, whatever its language, it had no independent meaning itself. It meant in regard to race only what the Constitution meant.[33] Thus, instead of having to parse the stingy and unyielding language of Title VI ("no person shall be subjected to discrimination . . on the ground of race"), the Brennan group could turn their creative energies to interpreting the broad and vague language of the Fourteenth Amendment ("no person shall be denied the equal protection of the laws"), which provided much more wiggle-room for justifying racial preferences. The Brennan group persuaded one other member, Justice Powell, to join them in their view of Title VI. But Powell didn't agree with their view of the Constitution. He argued that the Medical School's policy was unconstitutional and voted that Bakke must be admitted. His vote, added to the four votes of the Stevens group, meant that Allan Bakke won his case and that Powell got to write the opinion of the Court. The Brennan strategy didn't reap the fruit it intended.

Against the leanings of the Brennan group, who would distinguish between "benign" and "malign" uses of race and deal leniently with the former, Powell insisted that the Fourteenth Amendment's promise of "equal protection of the law" must mean the same thing for all, black and white alike. To paraphrase Powell:

> The Constitution can tolerate no "two-class" theory of equal protection. There is no

> principled basis for deciding between classes that deserve special judicial attention and those that don't. To think otherwise would involve the Court in making all kinds of "political" decisions it is not competent to make. In expounding the Constitution, the Court's role is to discern "principles sufficiently absolute to give them roots throughout the community and continuity over significant periods of time, and to lift them above the pragmatic political judgments of a particular time and place . . . ."[34]

What, then, was the practical meaning of a "sufficiently absolute" rendering of the principle of equal protection? It was this: when the decisions of state agents "touch upon an individual's race or ethnic background, he is entitled to a judicial determination that the burden he is asked to bear on that basis is precisely tailored to serve a compelling governmental interest."[35]

Powell, with this standard in hand, then turned to look at the four reasons the Medical School offered for its special program: (i) to reduce "the historic deficit of traditionally disfavored minorities in medical schools and the medical profession;" (ii) to counter "the effects of societal discrimination;" (iii) to increase "the number of physicians who will practice in communities currently underserved;" and (iv) to obtain "the educational benefits that flow from an ethnically diverse student body."[36] Did any or all of them specify a goal precisely tailored to serve a compelling governmental interest?

As to the first reason, Powell dismissed it out of hand.

> If [the School's] purpose is to assure within its student body some specified percentage of a particular group merely because of its race or ethnic origin, such a preferential purpose must be rejected not as insubstantial but as facially invalid. Preferring members of any one group for no reason other than race or ethnic origin is discrimination for its own sake.

As to the second reason, Powell allowed it more force. A state has a legitimate interest in ameliorating the effects of past discrimination. Even so, contended Powell, the Court

> has never approved a classification that aids persons perceived as members of relatively victimized groups at the expense of other innocent individuals in the absence of judicial, legislative, or administrative findings of constitutional or statutory violations.[37]

And the Medical School

> does not purport to have made, and is in no position to make, such findings. Its broad mission is education, not the formulation of any legislative policy or the adjudication of particular claims of illegality. . . . [I]solated segments of our vast governmental structures are not competent to make those decisions, at least in the absence of legislative mandates and legislatively determined criteria.[38]

As to the third reason, Powell found it, too, insufficient. The Medical School provided no evidence that

the best way it could contribute increased medical services to underserved communities was by employing a racially preferential admissions scheme. Indeed, the Medical School provided no evidence that its scheme would result in any benefits at all to such communities.[39]

This left the fourth reason. Here Powell found merit. A university's interest in a diverse student body is legitimated by the First Amendment's implied protection of academic freedom. This Constitutional halo makes the interest "compelling." However, the Medical School's use of a racial and ethnic classification scheme was not "precisely tailored" to effect the School's interest in diversity, argued Powell.

> The diversity that furthers a compelling state interest encompasses a far broader array of qualifications and characteristics of which racial or ethnic origin is but a single though important element. [The Medical School's] special admissions program, focused solely on ethnic diversity would hinder rather than further attainment of genuine diversity.[40]

The diversity which provides an educational atmosphere "conducive to speculation, experiment and creation" feeds upon a nearly endless range of experiences, talents, and attributes that students might bring to campus. In reducing diversity to racial and ethnic quotas, the Medical School wholly misconceived this important educational interest.

In sum, although the last of the Medical School's four reasons encompassed a "compelling governmental interest," the School's special admissions program was not necessary to effect that interest. The special admissions program was unconstitutional. So concluded Justice Powell.

How, then, did the *Bakke* decision become the basis upon which universities across the land enacted -- or maintained -- racially preferential admissions policies?

If Powell had concluded with his assessment of the Medical School's four reasons, *Bakke* would have left university affirmative action in a precarious situation. However, when the California Supreme Court had earlier ruled on Bakke's lawsuit, it had ordered Bakke admitted and forbidden the Medical School to make any use of race or ethnicity in its admissions decisions. Powell thought this went too far. Given higher education's protected interest in "diversity," and given that a student's race or ethnicity might add to diversity just in the same way that her age, work and travel experiences, family background, special talents, fluency in several languages, athletic prowess, military service, and unusual accomplishments might add, Justice Powell vacated that portion of the California Supreme Court's order.

Then he added some dicta for guidance. If universities want to understand diversity and the role that race and ethnicity might play in achieving it, they should look to Harvard, proposed Powell, and he appended to his opinion a long statement of Harvard's diversity program. In such a program, Powell contended, racial or ethnic background might

> be deemed a "plus" in a particular applicant's file, yet it does not insulate the individual from comparison with all other candidates for the available seats. . . . This kind of program

> treats each applicant as an individual in the admissions process. The applicant who loses out on the last available seat to another candidate receiving a "plus" on the basis of ethnic background will not have been foreclosed from all consideration for that seat simply because he was not the right color or had the wrong surname. It would mean only that his combined qualifications . . . did not outweigh those of the other applicant. His qualifications would have been weighed fairly and competitively, and he would have had no basis to complain of unequal treatment under the Fourteenth Amendment.[41]

In these off-hand comments, universities saw a green light for pushing ahead aggressively with their affirmative action programs. Although Justice Powell's basic holding could not have been plainer (any system like the Medical School's that makes race a consistently decisive factor, or that assesses applications along two different tracks defined by race, or that uses numerical quotas fails Constitutional muster), by the mid-1980s universities across the land had in place systems of admissions and scholarship awards that exhibited some or all of these features. When the University of Maryland's Banneker scholarships -- awarded only to African American students -- were held in violation of the Constitution in 1974,[42] the house of cards forming university affirmative action began to fall. In 1996, the Court of Appeals for the Fifth Circuit struck down the University of Texas Law School's admissions program,[43] and in November of the same year the voters of California adopted Proposition 209, forbidding among other things all uses of race in the public university admissions system. In 1998, the voters of Washington enacted a similar measure. Also in 1998, the Court of Appeals for the First Circuit struck down a Boston plan assigning students to selective high schools by race.[44] In 2001, two more schools saw their admissions programs invalidated: the University of Georgia[45] and the University of Michigan Law School.[46] In many of the cases, universities were using schemes that contravened Justice Powell's own holding; they were giving more than a "plus" to race. However, the Fifth Circuit Court in *Hopwood* threw a cloud even over Justice Powell's small window for affirmative action, boldly asserting that the *Bakke* holding was now dead as law and that race could not be used at all in admissions.

6. Equality

Given Justice Powell's singular opinion, supported by no one else on the Court, and given the drift of Supreme Court decisions on racial preferences since 1978,[47] the *Hopwood* court was not outlandish, if a bit presumptuous, in declaring Powell's holding in *Bakke* dead. If the Supreme Court eventually confirms that Powell's holding is no longer the law, it is not likely either to exhume the arguments of Justice Brennan in *Bakke*. This would be a misfortune. They convey an interpretation of Constitutional equality that Justice Powell never fully engaged.

Brennan agreed with Powell that "equal protection" must mean the same thing -- that is, remain one rule -- whether applied to black or white. But the same rule applied to different circumstances need not yield the same results. Racial preferences created for different reasons and producing different outcomes need not all be judged in the same harsh, virtually fatal, manner.

Powell thought there was no principled way to distinguish "benign" from "malign" discrimination, but Brennan insisted there was. He argued that if the Court looked carefully at its past cases striking down Jim Crow laws, it would see the principle at work. What the Court found wrong in Jim Crow was that it served no purpose except to mark out and stigmatize one group of people as inferior. The "cardinal principle" operating in the Court's decisions condemned racial classifications "drawn on the presumption that one race is inferior to another" or that "put the weight of government behind racial hatred and separation."[48] Brennan agreed with Powell that no public racial classification motivated by racial animus, no classification whose purpose is to stigmatize people with the "badge of inferiority," could withstand judicial scrutiny. However, the Medical School's policy, even if ill-advised or mistaken, reflected a public purpose far different from that found in Jim Crow. The policy ought not be treated as though it were cut from the same cloth.

Brennan granted that if a state adopted a racial classification for the purpose of humiliating whites, or stigmatizing Allan Bakke as inferior and confining him to second-class citizenship, that classification would be as odious as Jim Crow. But the Medical School's policy had neither this purpose nor this effect. Allan Bakke may have been upset and resentful at losing out under the special plan, but he wasn't "in any sense stamped as an inferior by the Medical School's rejection of him." Nor did his loss constitute a "pervasive injury," in the sense that wherever he went he would be treated as a "second-class citizen" because of his color.[49]

In short, argued Brennan, the principle embedded in the Equal Protection Clause should be viewed as an *anti-caste principle*, a principle that uniformly and consistently rejects all public law whose purpose is to subject people to an inferior and degraded station in life, whether they are black or white. Of course, given the asymmetrical position of whites and blacks in our country, we are not likely to encounter laws that try to stigmatize whites as an inferior caste (much less succeed at it). But this merely shows that a principle applied to different circumstances produces different results. Given that the Medical School's program reflected an effort to undo the effects of a racial caste system long-enduring in America, it expressed a purpose of great social importance and should not be found Constitutionally infirm.[50]

Powell never successfully engaged this way of reading "Constitutional equality." His insistence on clear, plain, unitary, absolute principle does not cut against the Brennan view. The issue between them is not the consistency and stringency of the principle but its content. Does the Constitution say, "The state cannot deliberately burden someone by race unless it passes an almost-always fatal test," or does it say, "The state cannot deliberately burden someone by race if its purpose is to create or maintain caste"?[51]

If Powell did not answer Brennan, neither, in turn, did Brennan successfully address one of Powell's worries. Were the Brennan view to prevail, Powell feared, then people could be subjected without check to the half-baked plans of any public agency in the country determined to do its bit to "remedy" the effects of historical discrimination. People would have no protection against arbitrary and over-reaching "remedial" policies.

However, there was an opening offered in the *Bakke* opinion for protecting people against runaway

preferences without outlawing programs like the Medical School's, a middle way never seized by either side. Recall that Powell dismissed the second reason offered by the Medical School -- that the state has an interest in ameliorating the effects of past discrimination -- by dismissing the School itself as neither competent nor authorized to make findings of past harm and adopt remedies for them. In both respects he was right. But on his own terms, then, he was required to give a respectful hearing to a body that *was* competent and authorized to inquire and legislate. Thus, suppose the legislature of California, after due deliberation and inquiry, had decided that the state's public universities should use special admissions plans like the Medical School's to temper in small part the evils attendant on California's own past history of discrimination. The legislature's interest in such ameliorative goals was conceded by Powell to be weighty. Moreover, limited and modest race-conscious policies would work in harmony with the legislature's aim, not at cross-purposes with it, as the Medical School's quota scheme worked at cross-purposes with achieving "diversity" (understood in Powell's sense). Why shouldn't Powell accede to the Medical School's admissions program under this hypothetical? Indeed, had he offered dicta on this point rather than on diversity, he might have moved the affirmative action debate into a more fruitful arena of debate. Letting state legislatures, and only state legislatures, decide on the make-up of state affirmative action programs would have left the decision in the hands of those who are representative of the people (as university faculties are not), competent to take account of a full range of relevant political factors (as courts are not), and authorized to legislate for the whole public good (as neither courts nor subordinate public agencies are). Of course, as subsequent political events in California and Washington indicate, some states might have foresworn any kind of preferential affirmative action. But other state legislatures might have explicitly authorized the kind of affirmative action admissions schemes their own public universities have carried on in a veiled, if not *sub rosa*, manner for two decades.

If we turn away from Constitutional exegesis, are we likely to find in political theory itself any principle of equality implying that *every* use of racial preferences in *every* circumstance works an intolerable injustice? There is reason to think not. To see why, consider John Rawls' theory of justice-as-fairness. For our purposes, what is striking about the theory is the division of labor it involves. Its very broadest principles of liberty and equality are themselves unable to single out proper micro-allocations of social benefits and burdens. This is not a defect; this is their nature. What they *can* do is structure roles and institutions which then create the social and legal machinery for assigning rights and responsibilities. Rawls' principles require a constitution to secure equality of citizenship to each member of society, but leaves most other matters to legislative judgment. Thus, law that in form and fact makes some people "second-class citizens" would be unconstitutional, clearly, but this limitation doesn't block asking people to bear unequal burdens for the common good, not even unequal burdens premised on their race or ethnicity. Nor does Rawls' principle of fair equality of opportunity block such burdens, either, for, while ordinarily discouraging selection based on race or ethnicity, it can itself be limited in the name of achieving greater equality of opportunity (a point conceded by Goldman).

Will putting aside Rawls and looking farther afield likely yield an understanding of general equality adamantly inhospitable to every use of preferences? The prospects seem dim. As Georgia Warnke has recently argued, a general notion of equality can argue as much for affirmative action (and the social inclusion it effects) as against it (and the racial non-neutrality it involves).[52]

7. Diversity

In the second wave of public controversy, spanning the 1990s, the affirmative action debate has narrowed both in its terms and focus. The focus is now race and ethnicity, because the central quarrel is now about university admissions. The terms are concomitantly constrained, with defenders of affirmative action emphasizing the virtues of diversity[53] and opponents emphasizing the harms affirmative action imposes upon its very beneficiaries.[54]

This second wave of public debate has not produced a flurry of philosophical articles like the first one. Indeed, in two 1990s collections edited by philosophers, *Affirmative Action: Social Justice or Reverse Discrimination?* and *The Affirmative Action Debate*, most of the entries by philosophical writers represent work from the 1970s, with only a smattering from the 1980s and 1990s.[55] The debate of the 1990s has generated its share of print, but most of it has flowed from the pens of public intellectuals of one stripe or another or found home in the pages of law reviews. Nor has any of this work, by philosophers and nonphilosophers alike, departed from the templates established nearly thirty years ago.[56]

That "diversity" has played a prominent role in the revived debates about preferences is no surprise, given that "diversity" was the legal hook proffered to universities in 1978. How does diversity support university affirmative action? In a widely circulated report in 1996, Neil Rudenstine, president of Harvard University, justified Harvard’s commitment to diversity by invoking John Stuart Mill, who stressed the value of bringing "human beings in contact with persons dissimilar to themselves, and with modes of thought and action unlike those with which they are familiar." A diverse student body, argued Rudenstine, is as much an "educational resource" as a university’s faculty, library, and laboratories.[57]

This is the diversity spoken of by Justice Powell, a diversity of opinions, experiences, backgrounds, talents, aspirations, and perspectives represented on campus that fosters intense intellectual exchange, exploration, and growth among all students. Obviously, an individual’s ethnicity, race, or gender can bear on this sort of diversity just as her being a devout Christian, tuba player, fluent speaker of Farsi, reserve military officer, former Peace Corps volunteer, champion swimmer, and self-taught auto mechanic can bear on it. Thus, a college seeking to admit a diverse entering class would not want to be utterly blind to race, ethnicity, or gender.[58]

In recently defending itself in *Gratz v. Bollinger* against an attack on the way it admits students into its College of Literature, Science, and Arts, the University of Michigan relied heavily on the diversity argument, insisting that it had a compelling educational interest in achieving racial and ethnic diversity. It put into evidence findings by one of its psychology professors, Patricia Gurin, showing that

> students learn better in a diverse educational environment, and they are better prepared to become active participants in our pluralistic, democratic society once they leave such a setting. . . . [S]tudents who experienced the most racial and ethnic diversity in classroom settings and in informal interactions with peers showed the greatest engagement in active

> thinking processes, growth in intellectual engagement and motivation, and growth in intellectual and academic skills.[59]

These findings might seem dispositive. Racial and ethnic diversity furthers good education. But how much so? Is such diversity literally compelling or merely legally so.[60] In defending their affirmative action policies, universities must be careful not to commit themselves to claims that look dubious on second thought.

For example, is the University of Michigan contending that, without a steady 8 or 9 percent representation of African American undergraduates on campus, it wouldn't be able to offer an education adequately developing its students' intellectual skills and civic commitments? If the University makes this argument, does it then imply that students attending Morehouse College or Florida A&M University cannot receive excellent educations, intellectually and civically? After all, these campuses are not at all racially and ethnically diverse. Indeed, Morehouse is lacking in gender diversity as well, since it is a college for men.

Once we begin to attend to the extraordinary variety among institutions of higher education in America, we might conclude that no single pattern of diversity within a school is a *sine qua non* for students' intellectual growth and civic development. Having 8 or 9 percent African American undergraduates on campus may be an educational desideratum but not an imperative.

In fact, it is clear enough that, had Patricia Gurin's findings come out differently, the University of Michigan was not about to relax its target of 8 or 9 percent African American undergraduates. Although racial and ethnic diversity at Ann Arbor might enrich students' educational experiences, the main reason the University of Michigan strives for a reasonable representation of minorities on campus is because of the way it conceives of its mission: to prepare Michigan's future leaders.

The argument is straightforward:

- The leadership of the state ought roughly to represent the state's population.
- As the state's premier training ground for leadership, the University ought to graduate rising generations of future leaders that conform to this representational goal.
- To graduate such rising generations, it needs to admit racially and ethnically representative classes.

This is the "Michigan Mandate."[61] Racial and ethnic diversity aren't incidental contributors to a distinct academic mission; they are part of the mission of the University, just as educating young people from Michigan is part of the mission.

Likewise, the principal aim of the elite universities studied by William Bowen and Derek Bok in *The Shape of the River: Long-Term Consequences of Considering Race in College and University Admissions* was not, through vigorous affirmative action, to enhance the liberal learning of their students (although they welcomed this gain for all students). Their main motive for assuring that the numbers of blacks on their campuses would be more than token derived from their self-conceptions as institutions training

individuals who would some day take up leadership roles in the professions, arts, science, education, politics, and government.[62] The nation, they believe, will be stronger and more just with a leadership reflecting a broader racial and ethnic profile than it does now (and than it did twenty-five years ago).

But at what cost? Stephan and Abigail Thernstrom have argued that the cost is high and falls on the very persons affirmative action is supposed to benefit. Under-prepared blacks are thrown into academic environments where they cannot compete.[63] In the Thernstroms' view, race-blind admissions policies would result in a desirable "cascading," with African American students ending up at colleges and universities where the academic credentials of entering students matches their own. In their own study, Bowen and Bok show that cascading isn't necessarily a valuable phenomenon. In fact, at the schools they studied, the better the institution a student entered, whatever his academic credentials, the more likely he was to graduate and go on to further education and earn a good income.[64]

Of course, the select schools Bowen and Bok studied may be quite unrepresentative of the full range of colleges and universities that resort to racial preferences, and the cost-benefit ratio that holds for these schools may not hold for the rest.[65] Nor does cascading in general look like a bad thing, if James Traub's portrait of the University of California system after Proposition 209 indicates a generalizable effect.[66]

Although the full facts about affirmative action in the university remain contentious and under debate, the data provided by Bowen and Bok settle at least one matter. Switching to class-based affirmative action would not be a proxy for race-based affirmative action.[67] At every income level, white students possess better grades and SAT scores than blacks at that same level. Giving preference by social class would result, thus, in disproportionately more whites than blacks entering selective universities.

8. Desert Confounded, Desert Misapplied

The affirmative action debate throws up many ironies but one in particular should be noted. From the time in 1973 when Judith Jarvis Thomson conjectured that it was "not entirely inappropriate" that white males bear the costs of the community's "making amends" to blacks and women through preferential affirmative action, the affirmative action debate has been distracted by intense quarrels over *who deserves what*. Do the beneficiaries of affirmative action deserve their benefits? Do the losers deserve their loss?

Christopher Edley, the White House assistant put in charge of President Clinton's review of affirmative action policy in 1994-95, speaks of how, during the long sessions he and his co-workers put in around the conference table, the discussion of affirmative action kept circling back to the "coal miner's son" question.

> Imagine a college admissions committee trying to decide between the white [son] of an Appalachian coal miner's family and the African American son of a successful Pittsburgh neurosurgeon. Why should the black applicant get preference over the white applicant?[68]

Why, indeed? This is a hard question if one defends affirmative action in terms of compensatory or distributive justice. If directly doing justice is what affirmative action is about, then its mechanisms must be adjusted as best they can to reward individual desert and true merit. The "coal miner's son" example is meant to throw desert in the defender's face: here is affirmative action at work thwarting desert, for surely the coal miner's son -- from the hard scrabble of Harlan County, say -- has lived with far less advantage than the neurosurgeon's son who, we may suppose, has reaped all the advantages of his father's (or mother's) standing. Why should the latter get a preference?

A defender might answer in the way that Charles Lawrence and Mari Matsuda do: "All the talk about class, the endless citings of the 'poor white male from Appalachia,' cannot avoid the reality of race and gender privilege."[69] White privilege means that racial preferences really do balance the scales. Male privilege means that gender preferences really do make selections fairer. There must be *no* concession: in every case the loser in affirmative action is *not* the more deserving.[70]

Even Justice Brennan tried his hand at this argument, writing in *Bakke*:

> If it was reasonable to conclude -- as we hold that it was -- that the failure of minorities to qualify for admission at Davis under regular procedures was due principally to the effects of past discrimination, then there is a reasonable likelihood that, but for pervasive racial discrimination, . . . [Bakke] would have failed to qualify for admission even in the absence of Davis' special admissions program.[71]

Counterfactually, Bakke was not denied anything to which he had moral claim in the first place.

Just as Mary Anne Warren and James Rachels in the 1970s thought that the losers under affirmative action were losing only illicit privileges, and the gainers merely gaining what should have been theirs to start with, so Michel Rosenfeld in the 1990s, in his extended "dialogic" defense of affirmative action, echoed the same thought:

> Although affirmative action treats innocent white males unequally, it need not deprive them of any genuine equal opportunity rights. *Provided an affirmative action plan is precisely tailored to redress the losses in prospects of success [by blacks and women] attributable to racism and sexism, it only deprives innocent white males of the corresponding undeserved increases in their prospects of success* . . . . [R]emedial affirmative action does not take away from innocent white males anything that they have rightfully earned or that they should be entitled to keep.[72]

But preferential programs that give blanket preferences by race or gender are hardly precisely tailored to match desert and reward since, as Lawrence and Matsuda acknowledge, the white male "privilege" is "statistical."[73] Yet it is individuals, not statistical averages, who gain or lose in the admissions committee decisions and employment office selections.

More pointedly, why the persistence of this obdurate strategy of defense when real-world affirmative action has had no truck with it? The affirmative action programs legitimated under the Civil Rights Act, in both their nonpreferential and preferential forms, had -- and have -- a specific aim: to change institutions so that they can meet the nondiscrimination mandate of the Act. Selection by race or gender was -- and is -- a means to such change. To the extent that such selection also compensated individuals for past wrongs or put people in places they really deserved*, these are incidental by-products of a process aimed at something else*.

Similarly, when the Medical School offered four reasons in defense of the special admissions program that left Bakke on the outside, none of these reasons said anything about matching admissions and desert. The criteria of the special admissions program -- race and ethnicity -- were instruments to further ends: integrating the classroom, the profession, and the delivery of medical services; and breaking the chain of self-reproducing societal discrimination. If the neurosurgeon's son *because of his race* can advance each of these goals and the coal miner's son can not, then the selection decision is easy: pick the *black* neurosurgeon's son (however advantaged he may have been) over the *white* coal miner's son (even were he the most deserving creature imaginable). The aims of real-world affirmative action make race and ethnicity (and sometimes gender) salient, not personal desert or merit.

Notes to Affirmative Action

Notes

[1.] The legality of racial "set-asides" in public construction contracting remains an unresolved issue but the public in general is not aroused by the vicissitudes of the contracting process and the good or ill fortunes of construction firms.

[19.] See Sher, "Justifying Reverse Discrimination," 165ff.

[20.] Lisa Newton, "Reverse Discrimination as Unjustified," *Ethics*, 83 (July 1973), 310. Similar sentiments were expressed by Virginia Black:

> If it is irrational and unjust and cruel to fire someone because he is a black or she is a woman -- cases whose absurdity seems obvious -- then it is equally irrational and unjust and cruel to hire someone because be is a black or she is a woman. To appreciate the parallel, one has only to remember that to hire X *because* of color is, ipso facto, *not* to hire Y because of color. When inscribed in law, this is racism.

Virginia Black, "The Erosion of Legal Principles in the Creation of Legal Policies," *Ethics*, 84 (January 1974), 106

[21.] Eastland and Bennett, *Counting By Race*, 149. This idea that using racial preferences involved a kind of practical contradiction was given voice and support at the highest levels of government in the 1980s. William Bradford Reynolds, during his tenure as Assistant Attorney General for Civil Rights in the Reagan Administration, contended:

> [T]o those who argue that we must use race to get beyond racism . . . [h]istory teaches us all too well that such an approach does not work. It is wrong when the government bestows advantages on whites at the expense of innocent blacks; it assumes no greater claim of morality if the tables are turned … . Whatever group membership one inherits, it carries with it no entitlement to preferential treatment over those not similarly endowed with the same immutable characteristics. Any compromise of this principle is discrimination, plain and simple, and such behavior is no more tolerable when employed remedially, in the name of "affirmative action" or "racial balance," to bestow a gratuitous advantage on members of a particular group, than when it is divorced from such beneficence and for the most invidious of reasons works to one's disadvantage.

William Bradford Reynolds, "Individualism vs. Group Rights: The Legacy of *Brown*," *Yale Law Journal*, 93 (May 1984), 1004. While Reynolds found the proposition, "Use race to achieve a colorblind society," an assault on logic, he belonged to an administration whose defense policy -- like that of a long line of administrations -- was grounded on the proposition, "Prepare for war in order to have peace."

[26.] Title 42 United States Code Sec. 2000d. Title IX of the Education Amendments of 1972 promised the same protection against gender discrimination. See 20 USC 1681.

[27.] "(a) … It shall be … unlawful for an employer -- (1) to . . . refuse to hire or to discharge any individual, or otherwise to discriminate against any individual with respect to his compensation, terms, conditions, or privileges of employment, because of such individual's race, color, religion, sex, or national origin; or (2) to limit, segregate, or classify his employees or applicants in any way which would tend to deprive any individual of employment opportunities or otherwise adversely affect his status as an employee, because of such individual's race, color, religion, sex, or national origin … ." Title 42 USC Sec 2000e-2

[28.] *Griggs v. Duke Power Company*, 401 U.S. 424 (1971), at 430, 431. At issue in the case was the use of an aptitude test and a high-school graduation requirement to screen job applicants. Duke Power Company did not succeed in showing that the results of the aptitude test or the possession of a high school diploma bore any demonstrable relation to performance at such of its jobs as janitor, maintenance worker, and the like.

[29.] For a more extended discussion of goals and quotas, see Fullinwider, *The Reverse Discrimination Controversy*, 162-177.

[30.] Consider, for example, this 1969 court decision involving a union with a record of excluding blacks and Mexican-Americans. the court imposed an injunction that

> prohibit[ed] discrimination in excluding persons from union membership or referring persons for work; prohibit[ed] use of member's endorsements, family relationship or elections as criteria for membership; … ordered the development of objective membership criteria and prohibited new members … until developed; and ordered continuation of chronological referrals for work, with alternating white and Negro referrals until objective membership criteria are developed.

On appeal, the Court of Appeals for the Fifth Circuit upheld the lower court. In its view,

> [t]he District Court did no more than prevent future discrimination when it prohibited a continuing exclusion of Negroes through the application of an apparently neutral membership provision … which served no significant trade-related purpose. [Further] the District Court did no more [in barring new membership until objective criteria were developed] than ensure that the injunction against further racial discrimination would be fairly administered. Absent objective criteria … covert subversion of the purpose of the injunction could occur. The same administrative reasons support alternating white and Negro referrals … .

Asbestos Workers v. Vogler, 407 F. 2d 1047 (1960), at 1051, 1055. Each part of the lower court's order, including the part that required racially balanced referrals, harkened back to a single ground: the part was necessary to prevent future discrimination.

[31.] For a list of Circuit Court decisions embracing this theory, see Robert K. Fullinwider, "Achieving Equal Opportunity," in Robert K. Fullinwider and Claudia Mills, eds., *The Moral Foundations of Civil Rights* (Totowa, New Jersey: Rowman & Littlefield, 1986), 106-08 and accompanying footnotes.

[32.] Regents of the University of California v. Bakke, 438, U.S. 265 (1978). In 1974, the Court accepted for decision a similar case involving a race-preference policy at the University of Washington Law School. However, perhaps experiencing second thoughts, the Court then dismissed the case as moot (the plaintiff, admitted to the Law School by a lower court, was about to graduate). See *De Funis v. Odegaard*, 416 U.S. 312 (1974).

[33.] Unlike Title VII, which was grounded in the Interstate Commerce Clause of the Constitution, Title VI was grounded in the federal government's spending powers. Brennan relied on Congressional debate to argue for the substantive identity of Title VI, on the one hand, and the Fourteenth Amendment to the Constitution, which forbids states to discriminate, and the Fifth Amendment, which incorporates the Fourteenth Amendment's strictures and applies them to the federal government, on the other hand. The debate can be summed up in this rhetorical question: "Why should the government through its spending be subsidizing acts of private discrimination that it would be forbidden by the Constitution to do itself?" See 438 U.S. 265, at 329-336.

[34.] 438 U. S. 265, at 295-300 (Powell quoting from Archibald Cox, *The Role of the Supreme Court in American Government* [New York: Oxford University Press, 1976], 114).

[35.] 438 U.S. 265, at 300.

[36.] 438 U.S. 265, at 307.

[37.] 438 U.S. 265, at 308.

[38.] 438 U.S. 265, at 310. Here Powell suggests that the threshold for justified preferences under the Constitution is exactly the same as the one for their use under Title VII: preferences may be used by an institution to prevent its own present and future discrimination. Justice Scalia takes this suggestion to stand for the Court's current settled doctrine. See *Richmond v. J. A. Croson Company*, 488 U.S. 469 (1989) (Scalia concurring).

[55.] Francis J. Beckwith and Todd E. Jones, eds., *Affirmative Action: Social Justice or Reverse Discrimination?*" (Amherst, New York: Prometheus Books, 1997); Steven M. Cahn, ed., *The Affirmative Action Debate* (New York: Routledge, 1995). Of the twenty-two chapters in Cahn, only four postdate 1990; of the fifteen chapters in Beckwith and Jones, only one by a philosopher postdates 1990 (one other

reworks material written in the 1980s).

[56.] Some recent philosophical work on affirmative action: Albert G. Mosley and Nicholas Capaldi, *Affirmative Action: Social Justice or Unfair Preference?* (Lanham, Maryland: Rowman & Littlefield, 1996); Albert G. Mosley, "Policies of Straw or Policies of Inclusion? A Review of Pojman's 'Case Against Affirmative Action'," *International Journal of Applied Philosophy*, 12 (1998), 161-168; Louis Pojman, "Straw Man or Straw Theory? A Reply to Albert Mosley," *International Journal of Applied Philosophy*, 12 (1998), 169-80; Francis J. Beckwith, "The 'No One Deserves His or Her Talents' Argument for Affirmative Action," *Social Theory and Practice*, 25 (1999), 53-60; Sarah Stroud, "The Aim of Affirmative Action," *Social Theory and Practice*, 25 (1999), 385-408; Stephen Kershnar, "Strong Affirmative Action Programs and Disproportionate Burdens," *Journal of Value Inquiry*, 33 (1999), 201-209.

[57.] Neil Rudenstine, "Why a Diverse Student Body Is So Important," *Chronicle of Higher Education*, 42 (April 19, 1996), B1.

[58.] Elizabeth Anderson, in "The Democratic University: The Role of Justice in the Production of Knowledge," in Ellen Frankel Paul et al., eds. *The Just Society* (New York: Cambridge University Press, 1995), 186-219, makes a complementary argument. It parallels Rudenstine's, but emphasizes epistemic rather than educational considerations and applies to faculty and graduate students rather than undergraduates. "A knowledge claim gains objectivity and warrant," Anderson insists, "to the degree that it is the product of exposure to the fullest range of criticisms and perspectives … . Universities [should] recruit students and faculty to ensure broad representation of people from all walks of life, so that the products of inquiry are open to critical scrutiny and influence from the widest range of viewpoints, and so that the subjects and direction of inquiry are responsive to the widest range of interests" (203, 198). But Anderson goes further than simply commending broad representation. She maintains that

> [t]he internal knowledge-promoting aims of the university call for measures to promote equality of access by all groups in society to membership in its ranks. This is an argument for affirmative action in university admissions and faculty hiring that recognizes the positive contributions that members of oppressed groups can and do make to enhancing the objectivity of research. Equality of access through affirmative action policies is not, therefore, an external political goal that threatens to compromise the quality of research. It is a means to promote the objectivity of that research (198).

For a discussion of her argument, see Robert K. Fullinwider, "Diversity and Affirmative Action," *Report from the Institute for Philosophy and Public Policy*, 17 (Winter/ Spring 1997), 26-31.

[59.] *Gratz v. Bollinger*, 122 F. Supp. 2d 811 (2000), at 823.

[60.] Recall that Justice Powell put the university's interest in diversity under the umbrella of academic freedom which is protected by the First Amendment of the Constitution. It is this latter connection that

makes the university's interest legally "compelling." In this sense, the university's interest in admitting tuba players is as compelling as its interest in admitting racial minorities.

[61.] *Gratz v. Bollinger*, 135 F. Supp. 2d 790 (2001), at 796-797.

[68.] Christopher Edley, Jr., *Not All Black and White: Affirmative Action and American Values* (New York: Hill and Wang, 1996), 132ff. Edley's example involved a coal miner's daughter. I've changed the daughter to a son for expository purposes.

[69.] Charles R. Lawrence III and Mari J. Matsuda, *We Won't Go Back: Making the Case for Affirmative Action* (Boston: Houghton Mifflin Company, 1997), 199-1.

[70.] Bernard Boxill has insisted that merely receiving benefits produced by injustice is enough to make one personally liable to compensate the victim of injustice (Bernard Boxill, "The Morality of Reparations," *Social Theory and Practice*, 2 [Spring 1972], 113-123). And who is the victim of injustice? "We *know* that all blacks, lower class, middle class, and upper class, have been wronged by racial injustice" (Bernard Boxill, *Blacks and Social Justice* [Totowa, New Jersey: Rowman and Allanheld, 1984], 164). In "The Morality of Preferential Hiring," *Philosophy & Public Affairs*, 7 (Spring 1978), 251, Boxill argues that in affirmative action the correlation between "preferences received" and "compensation deserved," though not perfect, is very high.

Exploitation

To exploit others is to take unfair advantage of them. Although 'exploitation' has figured prominently in Marxist theories, it is frequently invoked in ordinary moral and political discourse. This entry surveys various definitions that have appeared in the literature, attempts to identify the core elements of exploitation, and then considers its moral force. .

Introduction

Consider these examples of alleged exploitation.

> 1. The president of Stanford University claimed that big-time college athletics "reeks of exploitation," because the universities gain a great deal of revenue from the services of the athletes while the athletes (whose graduation rate is much lower than that of non-athletes) gain little from their college experience. (Kennedy 1990)
>
> 2. Advocates for people with AIDS protested the (then) annual price of AZT ($8,000), a drug that was thought to slow the progress of HIV. It was claimed that the Burroughs-Welcome Co., which produces AZT, was exploiting people who were already suffering.
>
> 3. A newspaper article described the proliferation of "posh strip clubs," at which topless young women dance for the customers. It was both claimed and denied that these clubs were loci of exploitation. The article noted that many believe that such bars "exploit women." At the same time, "many dancers say their work is no more exploitative than

> most other forms of employment," and the owner of one bar remarked that "If anyone is being exploited it is the men, the guys buying into the fantasy of she really likes me." (*New York Times*, April 15, 1992, C.12)
>
> 4. *USA Today* featured an article advocating the legalization of organ sales, whereby a person could be paid cash for a kidney. One reply maintained that such a policy would "open wide the door to exploitation." (September 14, 1991)
>
> 5. When Mary Beth Whitehead refused to surrender her daughter (who was known as "Baby M"), as specified in her $10,000 surrogacy contract with William Stern, the case touched off extended public, legal, and philosophical discussion of surrogate motherhood. One commentator observed that "one of the most serious charges against surrogate motherhood contracts is that they exploit women." (Field 1989, 25)

Although we frequently claim that some act, practice, or transaction is exploitative, the concept of exploitation is typically invoked without much analysis or argument, as if its meaning and moral force were self-evident. They are not. Even if some or even all of these sorts of claims are true, we still need to ask why are they true? And if they are true, what follows? More precisely, we can ask two questions: (1) what are the truth conditions of an exploitation claim? (2) what is the moral force of an exploitation claim? Let me explain.

For present purposes, an *exploitation claim* refers to statements that A’s interaction with B is (or is not) wrongfully exploitative or to statements that presuppose such a claim. To say that colleges exploit student athletes is to make an exploitation claim. Susan Okin makes an exploitation claim when she says that our family system constitutes "the pivot of a societal system of gender that renders women vulnerable to dependency, exploitation, and abuse," for we must know what exploitation involves to determine whether this claim is true. (Okin 1989, 135-36).

The first task of a theory of exploitation is to provide the truth conditions for an exploitation claim. At least one such condition is a moral criterion: a transaction is exploitative only if it is *unfair*. Interestingly, however, the (moral) "fact" of exploitation settles less than meets the eye. We must also consider the *moral force* of exploitation. In particular, we can ask whether the state should prohibit exploitative transactions or refuse to enforce exploitative agreements. The wrongness of exploitation does not dictate the way in which these moral questions should be answered.

This entry focuses on exploitative transactions or relations rather than "systemic" or macro level exploitation. It also has little to say about the Marxist view of exploitation. There are two major reasons for taking a different tack. First, the moral core of the Marxist view of exploitation is not unique to Marxism. When Marxism claims that the capitalist class exploits the proletariat, it employs the ordinary notion that one party exploits another when it gets unfair and undeserved benefits from its transactions or relationships. On that, the entry will have something to say. Second, what is unique to Marxism -- its approach to *measuring* exploitation through calculations of surplus value -- is very problematic.

This entry does the following. It first surveys the definitional landscape that has been marked out and highlights the conceptual quarrels which have arisen in the literature. It then sketches a very rough and preliminary account of the elements of exploitation. Finally, it makes some brief remarks about the moral force of exploitation.

The Definitional Landscape

At the most general level, A exploits B when A takes unfair advantage of B. (I shall always refer to the alleged exploiter as A and to the alleged exploitee as B). One problem with such a broad account, as Arneson notes, is that there will "be as many competing conceptions of exploitation as theories of what persons owe to each other by way of fair treatment." (Arneson 1992, 350). We can gain a somewhat sharper view of the issues that we must confront if we consider a sampling of the accounts that appear in the literature.

> 1. "[T]o exploit a person involves the *harmful, merely instrumental utilization* of him or his capacities, for one's own advantage or for the sake of one's own ends." (Buchanan 1985, 87).
>
> 2. "It is the fact that the [capitalist's] income is derived through *forced, unpaid, surplus* [wage] labor, *the product of which the workers do not control*, which makes [wage labor] exploitive." (Holmstrom 1997, 357).
>
> 3. "Exploitation necessarily involves benefits or gains of some kind to someone … Exploitation resembles a zero-sum game, viz. what the exploiter gains, the exploitee loses; or, minimally, for the exploiter to gain, the exploitee must lose." (Tormey 1974, 207-08)
>
> 4. "Exploitation [in exchange] demands. . .that there is no reasonably eligible alternative [for the exploitee] and that the consideration or advantage received is incommensurate with the price paid. One is not exploited if one is offered what one desperately needs at a fair and reasonable price." (Benn 1988, 138).
>
> 5. "Exploitation of persons consists in … wrongful behavior [that violates] the moral norm of *protecting the vulnerable*." (Goodin 1988a, 147).
>
> 6. "There are four conditions, all of which must be present if dependencies are to be exploitable. First, the relationship must be *asymmetrical* … Second, … the subordinate party must *need* the resource that the superordinate supplies … Third, … the subordinate party must depend upon some *particular* superordinate for the supply of needed resources … Fourth, the superordinate … enjoys discretionary control over the resources that the subordinate needs from him…" (Goodin 1988b, 37).

7. "Common to all exploitation of one person (B) by another (A) . . . is that A makes a profit or gain by turning some characteristic of B to his own advantage…exploitation … can occur in morally unsavory forms without harming the exploitee's interests and … despite the exploitee's fully voluntary consent to the exploitative behavior. ." (Feinberg 1988, 176-79).

8. "Persons are exploited if (1) others secure a benefit by (2) using them as a tool or resource so as (3) to cause them serious harm." (Munzer 1990, 171)

9. "A society is exploitative when its social structure is organized so that unpaid labor is systematically forced out of one class and put at the disposal of another … On the force-inclusive definition of exploitation, any exploitative society is a form of slavery." (Reiman 1987, 3-4).

10. "[A] group is exploited if it has some conditionally feasible alternative under which its members would be better off." (Roemer 1986, 136)

11. "[E]xploitation is seen as the failure to pay labour its marginal product…" (Brewer 1987, 86).

12. "An exploitative exchange is… an exchange in which the exploited party gets less than the exploiting party, who does better at the exploited party's expense… [T]he exchange must result from social relations of unequal power … exploitation can be entered into voluntarily; and can even, in some sense, be advantageous to the exploited party." (Levine 1988, 66-67).

13. "[Capitalist] social relations … are exploitative, not only in the specific sense of extracting surplus labour, but in the more general sense of using someone as a means, utilizing her to detriment as a way of promoting one's own good… " (Kymlicka 1989, 114).

14. "Workers are exploited if they work longer hours than the number of labor hours employed in the goods they consume." (Elster 1986, 121).

15. "[E]xploitation forms part of an exchange of goods and services when 1) the goods and services exchanged are quite obviously not of equivalent value, and 2) one party to the exchange uses a substantial degree of coercion." (Moore 1973, 53).

16. "[E]xploitation is a psychological, rather than a social or an economic, concept. For an offer to be exploitative, it must serve to create or to take advantage of some recognized psychological vulnerability which, in turn, disturbs the offeree's ability to reason effectively." (Hill 1994, 637).

All these accounts are compatible with the view that "A wrongfully exploits B when A takes unfair advantage of B." But there are some important differences among them. Some accounts (10, 14) are technical definitions of exploitation that are specific to a Marxist approach. Although none of the accounts denies that exploitation requires a gain to the exploiter, only some (3, 8) specifically mention that criterion. Some accounts invoke the Kantian notion that one wrongfully exploits when one treats another instrumentally or merely as a means (1, 8, 13). On some accounts, the exploited party must be harmed (1, 2, 3, 8, 9, 12), whereas other accounts allow that the exploited party may gain from the relationship (4, 7, 11, 12, 15). On some accounts, the exploited party must be coerced (2, 4, 6, 9, 15), whereas others require at least a defect in the quality of the consent (12, 16), and another maintains that exploitation can be fully voluntary (7).

We should not put rigid constraints on what counts as exploitation, at least at the outset. While some exploitative transactions are harmful to the exploitee, we often call exploitative cases in which the exploitee seems to gain from the transaction. Indeed, it is arguable that exploitation would be of much less theoretical interest on a "no harm, no exploitation" rule. It is trivially true that it is wrong for A to gain from an action that unjustifiably harms or coerces B. And even a libertarian will grant that some harmful exploitation may be legitimately prohibited by the state, if only because it is harmful (or rights violating) rather than because it is exploitative. By contrast, it is more difficult to explain when and why it might be wrong for A to gain from an action that benefits B and to which B voluntarily consents. And it is certainly more difficult to explain why society might be justified in prohibiting such transactions or refusing to enforce some such agreements.

For these reasons, it will be useful to make two sets of distinctions. First, we can distinguish between *harmful exploitation* and *mutually advantageous exploitation*. By mutually advantageous exploitation, we refer to those cases in which the exploit*ee* gains from the transaction as well as the exploiter. The advantageousness of the transaction is mutual, not the exploitation. To use somewhat different terminology, exploitation is mutually advantageous only when the transaction is Pareto Superior, that is, a transaction that leaves all parties better off. We can similarly distinguish between *nonconsensual exploitation*, where the exploited party does not give voluntary (or valid) consent, say because of coercion or fraud, and *consensual exploitation*, where it appears that the exploited party has given voluntary and appropriately informed consent to the transaction.

It might be argued that it begs the question to assume that exploitation *can* be mutually advantageous and consensual. The objection fails. If we were to assume, for the sake of argument, that the word exploitation is best limited to cases in which the exploitee is harmed, nothing would have changed. We would *still* have to ask whether there are important distinctions between those cases which are (*ex hypothesi*) wrongly referred to as mutually advantageous *exploitation* and those mutually advantageous transactions that are not described in that way. It would remain an open question as to whether some mutually advantageous arrangements are wrongful and why they are wrongful. If one wants to claim that a mutually advantageous and consensual transaction cannot be *unfair*, then that is not a dispute over language. That is a substantive claim, but there is no reason to think that position is correct.

The Elements of Exploitation

Let us start with the claim that A exploits B when A takes unfair advantage of B. Taking unfair advantage could be understood in two ways. First, it may refer to some dimension of the *outcome* of the exploitative act or transaction, that is, the transaction is substantively unfair. And this, it seems has two elements: (1) the benefit to A and (2) the effect on B. We may say that the benefit to A is unfair because it is wrong for A to benefit at all from his act (e.g. by harming B) or because A's benefit is excessive relative to the benefit to B. Second, to say that A takes unfair advantage of B may imply that there is some sort of defect in the *process* by which the unfair outcome has come about, for example, that A has coerced B or defrauded B or has manipulated B. In the final analysis we may find that these three elements are not all necessary to account for exploitation, but they provide us with a way to begin.

Benefit to A

A cannot take *unfair* advantage of B unless A gets some *advantage* from B. We can see the relevance of the "benefit to A" by contrasting exploitation with other forms of wrongdoing, such as discrimination, abuse, and oppression. Let us say that A discriminates against B when A wrongly deprives B of some opportunity or benefit because of some characteristic of B that is not relevant to A's action. There was a period in American history in which many women became public school teachers because they were denied the opportunity to enter other professions such as law and medicine. To the extent that society benefitted (in one way) from the pool of highly qualified public school teachers, the discrimination may have been exploitative, even if unintentionally so. But if A refuses to hire B solely because of B's race, then it would be odd to say that A exploits B, for A does not gain from the wrong to B.

Consider abuse. It has been alleged that medical students are frequently abused by verbal insults and denigration and that this abuse may leave long-lasting emotional scars. It is also sometimes claimed that medical interns are exploited, that they work long hours for low pay. The contrast is just right. There is no reason to think that anyone gains (in any normal sense) from abuse, but it is at least plausible to think that the hospitals or patients gain from the exploitation of interns.

Let us say that A oppresses B when A deprives B of freedoms or opportunities to which B is entitled. If A gains from the oppressive relationship, as when A enslaves B, then A may both oppress and exploit B. But if A does not gain from the oppression, the oppression is wrong but not exploitative. We might say that the unemployed are oppressed, but unless we could specify the ways in which some gain from their lack of employment, the unemployed are not exploited. Marxists would claim that capitalists pay exploitative wages to the employed precisely because there is a "reserve army" of the unemployed with whom the employed must compete. But that merely confirms that they are exploited because the oppression generates a gain to the capitalist class, and it is the employed who are exploited and not the unemployed that make such exploitation possible.

The Effect on B

As our definitional survey indicated, some commentators maintain that exploitation resembles a zero-sum game, that the exploiter gains what the exploitee loses. (Tormey, 207) Others maintain that exploitation is always harmful to the exploitee, even if the gains and losses do not cancel out. It is relatively uncontroversial that exploitation *can* be harmful to B, as in slavery. Other cases are more controversial. There are cases in which B is not directly affected by A's utilization of B, what Feinberg refers to as *harmless parasitism*, as when A follows B's taillights in a dense fog. A uses B to his own advantage, but does not render B worse off (assume that B is not bothered by A's headlights in B's mirror). (Feinberg, 14) In other cases of non-harmful exploitation, the transaction appears to benefit both A and B, as may be true of organ sales or commercial surrogacy.

Now in asking how A's action affects B's interests, we must be careful to adopt an *all things considered* point of view. There are, after all, negative *elements* in virtually all uncontroversially beneficial transactions. Paying money for a good that is clearly worth the price is still a negative element in the transaction. It would be better to get it for free. If A and B enter into a cooperative agreement where A gives B $100 for a book that is worth a lot to A (because it completes a collection) but is worth little to B, we do not say that B has been harmed by the transaction just because B has lost her book any more than we say that A has been harmed because the transaction required A to pay $100. Similarly, we do not say that a worker is harmed by employment merely because the worker prefers leisure to work. If the benefits to B from employment are greater than the costs to B, then employment is beneficial to B, all things considered. So in deciding whether a case of alleged exploitation should be classified as harmful exploitation or mutually advantageous exploitation, we must look at its net effect on B. If the benefits of a transaction exceed its costs, then it is not harmful even if it is exploitative, as might be true of organ sales and working as a stripper.

Joel Feinberg argues that if a transaction is mutually advantageous, then A does not gain at B's expense. (Feinberg 1988, 178). Not quite. There is an important sense in which any *marginal* gain to one party *within* a "zone of agreement" is always at the other party's expense. For while the parties may prefer any outcome within the zone of agreement to the non-agreement solution, they are not indifferent to the terms of the agreement. Mutually advantageous exploitation occurs when A and B gain relative to the non-cooperation baseline, but where the distribution of the benefits between A and B is unfair to B. Consider a garden variety case of alleged exploitation. An unexpected blizzard hits an area and people rush to the hardware store to buy a shovel. The hardware store owner sees the opportunity to make an abnormal profit and raises the price of a shovel from $15 to $30. If B agrees to pay $30 for the shovel, because the shovel is worth more than $30 to B under the circumstances, then the transaction is advantageous to both parties. If B is exploited, it is because B has paid too much. A similar structure applies to some of the other cases of alleged exploitation with which we began -- AZT for AIDS, surrogacy, organ sales. We need not deny that B benefits from these transactions, all things considered. Rather, A may exploit B if B pays too a high price for what she gains or does not receive enough for what she gives.

A mutually advantageous transaction is arguably (wrongly) exploitative only if the outcome is (in some way) unfair to B. This is not merely definitional. After all, it may be thought that a transaction is exploitative whenever takes advantage of B's vulnerabilities or desperate situation to strike a deal. That

is false. For if A makes a *reasonable* proposal that B has no alternative but to accept given B's desperate situation, A does not exploit B. If a doctor proposes to perform life-saving surgery for a reasonable fee, the patient is hardly exploited, even though the patient would not have agreed but for the fact that her life was in danger.

It might be said that "mutually advantageous" exploitation can and should be understood as a form of harmful exploitation. If we evaluate a transaction by reference to a *fairness baseline* as contrasted with a *no-transaction baseline*, then B is harmed when she pays $30 for a shovel by comparison with the fairness baseline (say, where B pays $15 for a shovel) even if B gains by comparison with the no-transaction baseline. Such relabeling would not change anything, for we would still have to distinguish between those cases in which B is harmed relative to both the fairness baseline and the no-transaction baseline and those cases where B is harmed only by reference to the fairness baseline but not by reference to the no-transaction baseline.

It may also be objected that the proposed distinction between harmful exploitation and mutually advantageous exploitation ignores a deeper -- Kantian -- way in which "mutually advantageous" exploitation is harmful to B, namely that A treats B merely as a means to be utilized to his own advantage rather than as an end in herself -- if so treating a person is to harm her. Allen Buchanan argues that exploitation occurs "whenever persons are harmfully utilized as mere instruments for private gain," and adds that this could apply to business transactions between two affluent bankers --"Each harmfully utilizes the other as a mere means to his own advantage." (Buchanan, 1984, 44.)

It is not clear what to make of this view. First, on one plausible reading of the Kantian maxim, one treats another as a mere means only when one treats "him in a way to which he could not possibly consent," as in cases of coercion and fraud, where A seeks to undermine B's capacity as an autonomous decision-maker. (Korsgaard 1993, 40). There is no reason to think that each banker could not possibly consent to be so treated by the other banker. Second, to say that A exploits B when A "harmfully utilizes" B as a "mere means" is equivocal as to whether "harmfully" is a reinforcing or modifying adverb. On one view, "harmfully" is merely reinforcing because the utilization of B merely as a means *constitutes* an independent harm to B. On another view, "harmfully" is a modifying adverb, because we can contrast the cases in which A harmfully utilizes B as a mere means with cases in which A non-harmfully utilizes B as a mere means. If we accept the first interpretation, we would still want to distinguish between those cases in which B is harmed apart from being treated merely as a means from those in which B is not harmed apart from the harm that derives from being treated merely as a means. On the second view, the bankers may utilize each other as means, but absent an independent form of harm, there is no reason to think that they are harmed by their utilization as a means itself. So that Kantian view does nothing to deny the distinction between harmful exploitation and mutually advantageous exploitation.

And so it seems better simply to grant that some allegedly exploitative transactions are mutually advantageous and go on to ask what makes a mutually advantageous transaction unfair. This is not easy because there is no non-problematic account of fair transactions. (Wertheimer 1996). Here are several possibilities.

We might say that a transaction is unfair when the goods exchanged are "incommensurable," as might be thought of the exchange of an organ for money. There are two problems here. First, it is not clear whether goods are ultimately incommensurable (Chang 1997). Second, if goods are incommensurable, it is not why an exchange of those goods is unfair.

Assuming that we can compare the gains of the parties, it is frequently suggested that a transaction is exploitative when A gains much more than B. But if we measure the parties' gains in terms of marginal utility from the no transaction baseline, the exploitee often gains more than the exploiter. If a doctor overcharges for life-saving surgery, exploiting the patient's situation, the doctor gains less than the patient. If a store owner charges $30 for a shovel, the buyer may well get more utility from the shovel than the seller gets for the money. Indeed, the exploiter's power over the exploitee stems precisely from the fact that he does not stand to gain too much. He can easily walk away from the transaction, whereas the exploitee cannot.

This suggests that we cannot evaluate the fairness of a transaction solely by comparing the gains of the parties. Rather, we must measure the fairness of their gains against a normative baseline as to how much the parties ought to gain, and that baseline is not easy to specify. A promising but not unproblematic candidate is to measure the parties' gains against what they would have gained in a "hypothetical competitive market," where there was relatively complete information. On this view, there is no independent standard of a "just price" for goods such as a shovel or a kidney, nor need we accept whatever the actual market yields, given the market's sundry imperfections. Rather, we evaluate the parties' gains by what they would have received under relatively perfect market conditions, just as we may try to determine the "fair market value" or a home by what the home would sell for under relatively perfect market conditions in that locale.

It might be thought that exploitation (at least when it is morally objectionable) is cofined to cases in which the exploitee is less well-off than the exploiter. Although most cases of exploitation will probably fit this pattern, exploitation is not confined to such cases. We might think, for example, that a store owner who charges an exorbitant price for the snow shovel is exploiting the customer, even if the customer is much wealthier than the store owner. On the present view, exploitation is transaction specific.

Although I am not sure that any available account of fair transactions provides the solution we need, some transactions are intuitively quite unfair even though they are advantageous to both parties. So let us assume that, in principle, some account of unfair transactions can be given. The question now arises as to whether an unfair transaction is always exploitative or whether A exploits B only if there is some defect in the process that culminates in B's decision.

Process

As we have seen, it seems plausible to argue that A does not exploit B simply because there is unfairness in the distribution of rewards. If B voluntarily agrees to what might otherwise be a maldistribution of advantages, as when B voluntarily decides to make a gift of goods or labor to A, then it seems wrong to

say that A has exploited B. It would, for example, be odd (although perhaps not impossible) to claim that a hospital exploits its volunteer workers just because the workers are volunteers rather than paid employees. So it seems that a relationship or transaction is exploitative only if there is some defect in the process by which it came about.

Interestingly, both Marxists and libertarians accept the view that voluntary transactions cannot be exploitative. Marxists tend to adopt a "force inclusive definition" of exploitation. Marxists do not say that capitalists exploit their workers *in spite* of the fact that the workers voluntarily agree to their employment status. They argue that workers are exploited only because they do not voluntarily agree to their employment status. Marxists concede that the proletariat is not enslaved, because they are not tied to any particular employer, but they transfer their labor to the capitalist under the "dull compulsion of economic relations." (Elster 1983, 277-78). Libertarians can be understood as accepting this "force inclusive" definition of exploitation, but come to the opposite conclusion. They maintain that since market transactions are not coerced, the workers are therefore not exploited. We do not need to accept these alternatives. Leaving aside just how to distinguish between nonconsensual and consensual exploitation, A can arguably exploit B even if B is not coerced (or defrauded), even if there is nothing untoward about B’s decision within her objective situation.

Let us press this issue a bit further. There are some instances of alleged exploitation in which the issue of consent does not seem to arise. There are cases in which the exploitee may be entirely passive. A may sell photographs of B without B’s knowledge, or rob a purse from a sleeping B or follow B’s taillights in a dense fog. In these cases, B’s will is not involved. Call this nonvolitional exploitation. If nonvolitional exploitation operates *without* the engagement of B’s will, then nonconsensual exploitation operates *against* B’s will, as when A coerces B or deceives B. The question now arises as to when there is such a procedural defect.

In general, A coerces B to do X only if A proposes (threatens) to make B worse off with reference to some baseline condition if B chooses not do X, although specifying the appropriate baseline against which to measure the proposal can be a complicated matter. (Wertheimer, 1987) If A gets B to pay A $100 per week by threatening to bomb B’s store if he does not pay up, then A coerces B into paying $100 a week. By contrast, if A gets B to pay A $100 per week by proposing to clean B’s store each night, then A has made a non-coercive (or inducive) offer to B. A does not propose to worsen B’s situation if B rejects A’s proposal. On this view, A does not coerce B in the cases involving organ sales or commercial surrogacy, because A does not propose to worsen B’s situation if B rejects A’s proposal.

Fraud also undermines the validity of B’s consent. Suppose that A offers to sell B a car for $10,000. A tells B that the car has been driven only 50,000 miles, but has set back the odometer from 90,000 to 50,000. B has not given valid consent, because valid consent must be informed (or not misinformed) as well as uncoerced.

By contrast with cases of coercion and fraud, there are at least some cases of alleged exploitation in which B’s consent is not defective in either of these ways. In many cases of alleged exploitation, A gets

B to agree to a mutually advantageous transaction to which B would not have agreed under better or perhaps more just background conditions, where A has played no direct causal role in creating those circumstances, where A has no special obligation to repair those conditions, and where B is fully informed as to the consequences of various choices. Although B might prefer to have a different range of options available to him, she can make a perfectly rational choice among the various options. Such conditions may (or may not) obtain in cases such as commercial surrogacy, organ sales, and, say, our snow shovel case.

It might be objected that perfectly rational and (otherwise) uncoerced choices are not appropriately consensual if made under conditions of desperation or from an inequality of bargaining power, or under unjust background conditions. But even if we refer to such transactions as nonconsensual, we would still have to contrast the cases that are nonconsensual because of coercion or fraud and those that are allegedly nonconsensual in other ways. And we will still have to ask what the moral force of such exploitation amounts to: Should we prohibit A from making such proposals? Should we refuse to enforce agreements made under such conditions? And that brings us to the moral force of exploitation.

The Moral Force of Exploitation

I have suggested that exploitation provides a moral description of a transaction, but that its moral force is less clear. The moral force of harmful and nonconsensual exploitation is relatively unproblematic. Whatever the added moral importance of the gain to A from the harm to B, it is certainly at least *prima facie* wrong for A to harm B and it seems that the state is at least *prima facie* justified in prohibiting or refusing to enforce such transactions.

Mutually advantageous transactions present a more difficult set of problems. Even if a transaction between A and B is unfair, it might be thought that there can be nothing *seriously* wrong about an agreement from which both parties benefit, particularly if A has no obligation to enter into any transaction with B. Moreover, even if there is something seriously wrong about such transactions, it might be argued that it could not be a wrong that would justify state intervention. Recall the snow shovel case. Even if A acts wrongly or fails to act virtuously, it is arguable that A does not harm anyone or violate anyone's rights, and only harm or rights violations justify state intervention. If the state cannot force A to sell the shovel to B, it might be thought completely *irrational* for the state to prohibit A and B from entering into a consensual and mutually advantageous transaction.

Perhaps this view is correct. Bracketing arguments based on externalities, it seems perfectly plausible to maintain that the state is justified in interfering with transactions only if one party is violating the other's rights. That said, those who invoke the concept of exploitation frequently maintain that such exploitation provides a reason for state intervention. For example, when it is claimed that commercial surrogacy exploits the birth mothers, the critics typically argue that surrogacy contracts should be unenforceable or entirely prohibited. Similar things are said about the sale of bodily organs. Those who make such arguments do frequently claim that the transactions are nonconsensual or harmful, but they seem prepared to make such arguments even if the transactions are consensual and mutually advantageous.

On what grounds might we justify interfering with consensual and mutually advantageous exploitative transactions? It might be thought that we could interfere on paternalistic grounds. A paternalistic argument could not justify interfering with exploitative transactions if the exploitative transaction is advantageous to the exploitee and if interference is not likely to result in a transaction that is more beneficial to B. For paternalism justifies interfering for someone's good, and this interference would not be to the target's benefit. But there might be situations in which B knows enough to agree only to those exploitative transactions that are beneficial (as compared with no transaction), but does not know that less exploitative transactions are available. And so there may be a "soft paternalist" justification for interference with some mutually advantageous exploitative transactions.

We might also justify interfering with exploitative transactions on strategic grounds. Suppose that A enjoys a monopoly position, say, as a potential rescuer of B. If we prohibit A from charging an exorbitant price for his services, then A might offer his services for a reasonable price. This argument would not justify interfering in a highly competitive market, for, under such conditions, A would not and could not offer his services for a better price. But there may be numerous situations in which such strategic arguments can work. (Wertheimer 1996).

Can we justify interfering with mutually advantageous and consensual transactions on perfectionist or moralistic grounds? That is more difficult. Joel Feinberg has maintained that because mutually advantageous exploitation is not harmful, such exploitation would constitute a "free-floating evil," a wrong that is bad for no one. "In these cases there is no wrongful loss for the exploitee, who can himself have no grievance." (Feinberg 1988, 176). There are two questions here: is mutually advantageous exploitation a free-floating evil? and free-floating or not, can we justify interfering with immoral transactions on the ground that they are immoral?

Is mutually advantageous exploitation a free-floating evil? I think not. Suppose that B and C both need blood transfusions, and that the only available blood is compatible with B's blood type, but not with C's blood type. There are only two possible worlds: (1) No Transfusion, where neither B nor C gets a transfusion; (2) Transfusion, where B gets the transfusion and C does not. In this case, to say that it would be wrong -- in any way -- to give the transfusion to B would seem to involve a "free-floating evil." Giving the transfusion to B is good for B and bad for no one, including C, for there is no feasible alternative world in which C could have gained.

But the world of mutually advantageous exploitation is not like this. Recall the "snow shovel" example. Here there are, let us say, three feasible alternative worlds: (1) Transaction 1, where A sells B a shovel for an exorbitant $30; (2) Transaction 2, where A sells B a shovel for the normal price of $15; (3) no transaction. Is Transaction 1 better for A and worse for no one? Yes and No. Yes, when compared to the No Transaction baseline. No, when compared with Transaction 2. By comparison with Transaction 2, the "wrong" in Transaction 1 is not free floating. B is not harmed in Transaction 1, but B's interests are clearly negatively affected by A's choice to engage in Transaction 1 as contrasted with Transaction 2. To say that the wrong involved in mutually advantageous exploitation is not free floating does not establish its moral force. There might be good reason for the state to stay its hand. But even if there are good

reasons not to interfere with most cases of mutually advantageous exploitation, it does not follow that exploitation is morally trivial. The disposition not to take unfair advantage of one's fellows may be among the more important moral virtues and a necessary condition of civilized life, even if there are also good reasons for not penalizing the failure to display that virtue.

Even if exploitation is seriously wrong, it may not be the worst form of injustice or inequality. Suppose that social justice requires a relatively egalitarian distribution of resources. If an inequality between A and B is exploitative only if there is some causal relationship between A's and B's positions, then many injustices will have nothing to do with exploitation. Although it may be unjust that A has much more than B, A's having more may have nothing to do with B's having little. Consider the exploitation of labor. Some people are more productive than others, albeit often because of morally irrelevant factors, such as social background or native talents.

If we exploit people when we fail to reward them in proportion to their productive contribution, then the low contributors may not be exploited. (Nagel 1991, 99-100) Indeed, if the high contributors are taxed to provide for the needs of the low contributors, they might maintain that it is they who are being exploited. Consider the unemployed. If the unemployed are not exploited because they "do not produce any surplus value for the capitalist to appropriate," we may well conclude that being excluded from the labor system is much worse than being exploited in the system. (Kymlicka, 176). Still, even if exploitative inequality is not always morally worse than non-exploitative inequality, it is an interesting and important question as to whether and in what ways the inequalities and suffering that arise from exploitation have a special call on our moral attention.

Non-Monotonic Logic

The term "non-monotonic logic" covers a family of formal frameworks devised to capture and represent *defeasible inference*, i.e., that kind of inference of everyday life in which reasoners draw conclusions tentatively, reserving the right to retract them in the light of further information. Such inferences are called "non-monotonic" because the set of conclusions warranted on the basis of a given knowledge base does not increase (in fact, it can shrink) with the size of the knowledge base itself. This is in contrast to classical (first-order) logic, whose inferences, being deductively valid, can never be "undone" by new information.

Abstract Consequence relations

Classical first-order logic (henceforth: FOL) is monotonic: if a sentence φ can be inferred in FOL from a set Γ of premises, then it can also be inferred from any set Δ of premises containing Γ as a subset. In other words, FOL provides a relation $\models$ of *consequence* between sets of premises and single sentences with the property that if $\Gamma \models \varphi$ and $\Gamma \subseteq \Delta$, then $\Delta \models \varphi$. This follows immediately from the nature of the relation $\models$, for $\Gamma \models \varphi$ holds precisely when φ is true on every interpretation on which all sentences in Γ are true (see the entry on classical logic for details on the relation $\models$).

From an abstract point of view, we can consider the formal properties a consequence relation. Let $\mid\!\sim$ be any relation between sets of premises and single sentences. It is natural to consider the following properties, all of which are satisfied by the consequence relation $\models$ of FOL:

- **Supraclassicality**: if $\Gamma \models \varphi$ then $\Gamma \mid\!\sim \varphi$.

- **Reflexivity**: if $\varphi \in \Gamma$ then $\Gamma \mathrel{|\!\!\sim} \varphi$;
- **Cut**: If $\Gamma \mathrel{|\!\!\sim} \varphi$ and $\Gamma, \varphi \mathrel{|\!\!\sim} \psi$ then $\Gamma \mathrel{|\!\!\sim} \psi$;
- **Monotony**: If $\Gamma \mathrel{|\!\!\sim} \varphi$ and $\Gamma \subseteq \Delta$ then $\Delta \mathrel{|\!\!\sim} \varphi$.

Supraclassicality just requires that $\mathrel{|\!\!\sim}$ be an extension of $\models$, i.e., that if φ follows from Γ in FOL, then it must also follow according to $\mathrel{|\!\!\sim}$. (The relation $\models$ is trivially supraclassical).

The most straightforward of the remaining conditions is reflexivity: we certainly would like all sentences in Γ to be inferable from Γ. This translates to the requirement that if φ belongs to the set Γ, then φ is a consequence of Γ. Reflexivity is a rather minimal requirement on a relation of logical consequence: It is hard to imagine in what sense a relation that fails to satisfy reflexivity, can still be considered considered a *consequence* relation.

Cut, a form of transitivity, is another crucial feature of consequence relations. Cut is a conservativity principle: if φ is a consequence of Γ, then ψ is a consequence of Γ together with φ only if it is already a consequence of Γ alone. In other words, by adjoining to Γ something which is already a consequence of Γ does not lead to any *increase* in inferential power.

Cut is best regarded as a condition on the "length" of a proof (where "length" is to be understood in some intuitive sense related to the complexity of the argument supporting a given conclusion). When viewed in these terms, Cut amounts to the requirement that the length of the proof does not affect the degree to which the assumptions support the conclusion. Where φ is already a consequence of Γ, if ψ can be inferred from Γ together with φ, then ψ can also be obtained via a longer "proof" that proceeds indirectly by first inferring φ.

In many forms of probabilistic reasoning the degree to which the premises support the conclusion is inversely correlated to the length of the proof. For this reason, many forms of probabilistic reasoning fail to satisfy Cut. To see this, we adapt a well-known counter-example: let *Ax* abbreviate "*x* is a Pennsylvania Dutch", *Bx* abbreviate "*x* is a native speaker of German", and *Cx* abbreviate "*x* was born in Germany". Further, let Γ comprise the statements "Most *A*s are *B*s," "Most *B*s are *C*s," and *Ax*. Then Γ supports *Bx*, and Γ together with *Bx* supports *Cx*, but Γ by itself does not support *Cx*. (Here statements of the form "Most *A*s are *B*s" are interpreted probabilistically, as saying that the conditional probability of *B* given *A* is, say, greater that 50%.) To the extent that Cut is a necessary feature of a well-behaved consequence relation, examples of inductive reasoning such as the one just given cast some doubt on the possibility of coming up with a well-behaved relation of probabilistic consequence.

For our purposes, Monotony is the central property. Monotony states that if φ is a consequence of Γ then it is also a consequence of any set containing Γ (as a subset). The import of monotony is that one cannot pre-empt conclusions by adding new premises. However, there are many inferences typical of everyday (as opposed to mathematical or formal) reasoning, that do not satisfy monotony. These are cases in which we reach our conclusions *defeasibly* (i.e., tentatively), reserving the right to retract them in the light of

further information. Perhaps the clearest examples are derived from legal reasoning, in which defeasible assumptions abound. In the judicial system, the principle of *presumption of innocence* leads us to infer (defeasibly) from the fact that *x* is to stand trial, the conclusion that *x* is innocent; but clearly the conclusion can be retracted in the light of further information.

Other examples are driven by typicality considerations. If being a B is a typical trait of A's, then from the fact that *x* is an A we infer the conclusion that *x* is a B. But the conclusion is defeasible, in that B-ness is not a necessary trait of A's, but only (perhaps) of 90% of them. For example, mammals, by and large, don't fly, so that lack of flight can be considered a typical trait of mammals. Thus, when supplied with information that *x* is a mammal, we naturally infer that *x* does not fly. But this conclusion is defeasible, and can be undermined by the acquisition of new information, for example by the information that *x* is a bat. This inferential process can be further iterated. We can learn, for instance, that *x* is a baby bat, that does not know how to fly yet.

Defeasible reasoning, not unlike FOL, can follow complex patterns. However, such patterns are beyond reach for FOL, which is, by its very nature, monotonic. The challenge then is to provide for defeasible reasoning what FOL provides for formal or mathematical reasoning, i.e., an account that is both materially adequate and formally precise.

The conclusion of the preceding discussion is that monotony has to be abandoned, if we want to give a formal account of these patterns of defeasible reasoning. Then the question naturally arises of what formal properties of the consequence relation are to replace monotony. Two such properties have been considered in the literature, for an arbitrary consequence relation $\mid\sim$:

- **Cautious Monotony**: If $\Gamma \mid\sim \varphi$ and $\Gamma \mid\sim \psi$, then $\Gamma, \varphi \mid\sim \psi$.
- **Rational Monotony**: If it's not the case that $\Gamma \mid\sim \neg \varphi$, and moreover $\Gamma \mid\sim \psi$, then $\Gamma, \varphi \mid\sim \psi$.

Both Cautious Monotony and the stronger principle of Rational Monotony are special cases of Monotony, and are therefore not in the foreground as long as we restrict ourselves to the classical consequence relation $\models$ of FOL.

Although superficially similar, these principles are in reality quite different. Cautious Monotony is the converse of Cut: it states that adding a consequence φ back into the premise-set Γ does not lead to any *decrease* in inferential power. Cautious Monotony tells us that inference is a cumulative enterprise: we can keep drawing consequences that can in turn be used as additional premises, without affecting the set of conclusion. Together with Cut, Cautious Monotony says that if φ is a consequence of Γ then for any proposition ψ, ψ is a consequence of Γ if and only if it is a consequence of Γ together with φ. It has been often pointed out, most notably by Dov Gabbay, that Reflexivity, Cut and Cautious Monotony are critical properties for any well-behaved non-monotonic consequence relation.

The status of Rational Monotony is much more problematic. As we observed, Rational Monotony can be regarded as a strengthening of Cautious Monotony, and like the latter it is a special case of Monotony.

However, there are reason to think that Rational Monotony might not be a correct feature of a non-monotonic consequence relation. A counter-example due to Robert Stalnaker (see Stalnaker (1994)) involves three composers: Verdi, Bizet, and Satie. Suppose that we initially accept (correctly but defeasibly) that Verdi is Italian, while Bizet and Satie are French. We assume that these defeasible conclusions are built into whatever inferential mechanism implements the non-monotonic relation $\mid\!\sim$.

Suppose now that we are told by a reliable source of information that that Verdi and Bizet are compatriots. This lead us no longer to endorse the propositions that Verdi is Italian (because he could be French), and that Bizet is French (because he could be Italian); but we would still draw the defeasible consequence that Satie is French, since nothing that we have learned conflicts with it. By letting I(v), F(b), and F(s) represent our initial beliefs about the composers' nationalities, and C(v,b) represent the proposition that Verdi and Bizet are compatriots, the situation could be represented as follows:

$$C(v,b) \mid\!\sim F(s),$$

Now consider the proposition C(v,s) that Verdi and Satie are compatriots. Before learning that C(v,b) we would be inclined to reject the proposition C(v,s) because we endorse and I(v) and F(s), but after learning that Verdi and Bizet are compatriots, we can no longer endorse I(v), and therefore no longer reject C(v,s). Then the following *fails*:

$$C(v,b) \mid\!\sim \neg C(v,s).$$

However, if we added C(v,s) to our stock of beliefs, we would lose the inference to F(s): in the context of C(v,b), the proposition C(v,s) is equivalent to the statement that all three composers have the same nationality. This leads us to suspend our assent to the proposition F(s). In other words, and contrary to Rational Monotony, the following also *fails*:

$$C(v,b), C(v,s) \mid\!\sim F(s).$$

The previous discussion gives a rather clear picture of the desirable features of a non-monotonic consequence relation. Such a relation should satisfy Supraclassicality, Reflexivity, Cut, and Cautious Monotony.

Skeptical or credulous?

A separate issue from the formal properties of a non-monotonic consequence relation, although one that is strictly intertwined with it, is the issue of how *conflicts* between potential defeasible conclusions are to be handled.

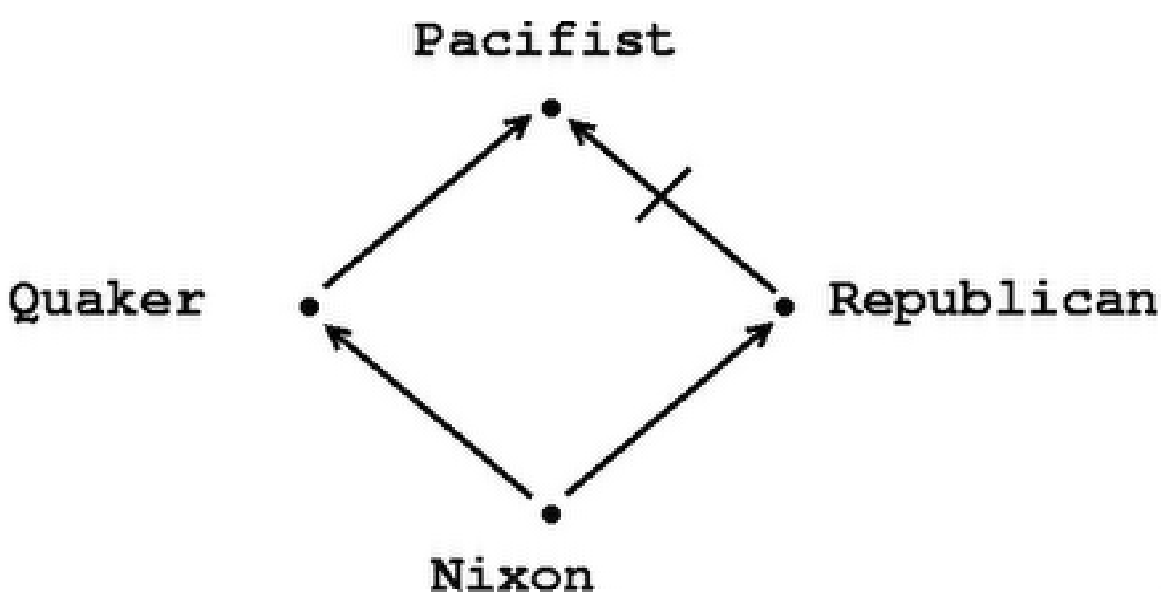
There are two different kinds of conflicts that can arise within a given non-monotonic framework: (*i*) conflicts between defeasible conclusions and "hard facts;" and (*ii*) conflicts between one potential

defeasible conclusion and another (many formalisms, for instance, provide some form of defeasible inference rules, and such rules might have conflicting conclusions). When a conflict (of either kind) arises, steps have to be taken to preserve or restore consistency.

All non-monotonic logics handle conflicts of the first kind in the same way: indeed, it is the very essence of defeasible reasoning that conclusions can be retracted when new facts are learned. But conflicts of the second kind can be handled in two different ways: one can draw inferences either in a "cautious" or "bold" fashion (also known as "skeptical" or, respectively, "credulous"). These two options correspond to significantly different ways to construe a given body of defeasible knowledge, and yield different results as to what defeasible conclusions are warranted on the basis of such a knowledge base.

The difference between these basic attitudes comes to this. In the presence of potentially conflicting defeasible inferences (and in the absence of further considerations such as specificity -- see below), the credulous reasoner always commits to as many defeasible conclusions as possible, subject to a consistency requirement, whereas the skeptical reasoner withholds assent from potentially conflicted defeasible conclusions.

A famous example from the literature, the so-called "Nixon diamond," will help make the distinction clear. Suppose our knowledge base contains (defeasible) information to the effect that a given individual, Nixon, is both a Quaker and a Republican. Quakers, by and large, are pacifists, whereas Republicans, by and large are not. The question is what defeasible conclusions are warranted on the basis of this body of knowledge, and in particular whether we should infer that Nixon is a pacifist or that he is not pacifist. The following figure provides a schematic representation of this state of affairs in the form a (defeasible) network:



The credulous reasoner has no reason to prefer either conclusion ("Nixon is a pacifist;" "Nixon is not a pacifist") to the other one, but will definitely commit to one or the other. The skeptical reasoner recognizes that this is a conflict not between hard facts and defeasible inferences, but between two different defeasible inferences. Since the two possible inferences in some sense "cancel out," the skeptical

reasoner will refrain from drawing either one.

Whereas many of the early formulations of defeasible reasoning have been credulous, skepticism has gradually emerged as a viable alternative, which can, at times, be better behaved. Arguments have been given in favor of both skeptical and credulous inference. Some have argued that credulity seems better to capture a certain class of intuitions, while others have objected that although a certain degree of "jumping to conclusion" is by definition built into any non-monotonic formalism, such jumping to conclusions needs to be regimented, and that skepticism provides precisely the required regimentation. (A further issue in the skeptical/credulous debate is the question of whether so-called "floating conclusions" should be allowed; see Horty (forthcoming) for a review of the literature and a substantial argument that they should not.)

Non-monotonic formalisms

One of the most significant developments both in logic and artificial intelligence, is the emergence of a number of non-monotonic formalisms, devised expressly for the purpose of capturing defeasible reasoning in a mathematically precise manner. The fact that patterns of defeasible reasoning have been accounted for in such a rigorous fashion has wide-ranging consequences for our conceptual understanding of argumentation and inference.

Pioneering work in the field of non-monotonic logics began with the realization that ordinary first-order logic is inadequate for the representation of defeasible reasoning accompanied by the effort to reproduce the success of FOL in the representation of mathematical, or formal, reasoning. Among the pioneers of the field in the late 1970's were (among others) J. McCarthy, D. McDermott & J. Doyle, and R. Reiter (see Ginsberg (1987) for a collection of early papers in the field and Gabbay et al (1994) for a more recent collection of excellent survey papers). In 1980, the *Artificial Intelligence Journal* published an issue (vol. 13, 1980) dedicated to these new formalisms, an event that has come to be regarded as the "coming of age" of non-monotonic logic.

If one of the goals of non-monotonic logic is to provide a materially adequate account of defeasible reasoning, it is important to rely on a rich supply of examples to guide and hone intuitions. Database theory was one of the earliest sources of such examples, especially as regards the *closed world assumption*. Suppose a travel agent has access to a flight database, and needs to answer a client's query about the best way to get from Oshkosh to Minsk. The agents queries the database and, not surprisingly, responds that there are no direct flights. How does the travel agent know?

It is quite clear that, in a strong sense of "know", the travel agent does not *know* that there are no such flights. What is at work here is a tacit assumption that the database is *complete*, and that since the database does not list any direct flights between the two cities, then there are none. A useful way to look at this process is as a kind of *minimization*, i.e., an attempt to minimize the extension of a given predicate ("flight-between," in this case). Moreover, on pain of inconsistencies, such a minimization needs to take place not with respect to what the database explicitly contains but with respect to what it implies.

The idea of minimization is at the basis of one of the earliest non-monotonic formalisms, McCarthy's *circumscription*. Circumscription makes explicit the intuition that, all other things being equal, extensions of predicates should be *minimal*. Again, consider principles such as "all normal birds fly". Implicit in this principle is the idea that the extension of the abnormality predicate should be minimal, and that specimens should not be considered to be abnormal unless there is positive information to that effect. McCarthy's idea was to represent this formally, using second-order logic (SOL). In SOL, in contrast to FOL, one is allowed to explicitly quantify over predicates, forming sentences such as $\exists P \forall x Px$ ("there is a universal predicate") or $\forall P(Pa \leftrightarrow Pb)$ ("*a* and *b* are indiscernible").

In circumscription, given predicates *P* and *Q*, we abbreviate $\forall x(Px \rightarrow Qx)$ as $P \leq Q$; similarly, we abbreviate $P \leq Q$ & $\neg Q \leq P$ as $P<Q$. If $A(P)$ is a formula containing occurrences of a predicate *P*, then the circumscription of *P* in *A* is the second-order sentence $A^*(P)$:

$$A(P) \mathbin{\&} \neg \exists Q\, [A(Q) \mathbin{\&} Q < P\,]$$

$A^*(P)$ says that *P* satisfies *A*, and that no smaller predicate does. Let *Px* be the predicate "*x* is abnormal," and let $A(P)$ be the sentence "All normal birds fly." Then the sentence "Tweety is a bird," together with $A^*(P)$ implies "Tweety flies," for the circumscription axiom forces the extension of *P* to be empty, so that "Tweety is normal" is automatically true.

In terms of consequence relations, circumscription allows us to define, for each predicate *P*, a non-monotonic relation $A(P) \mid\!\sim \varphi$ that holds precisely when $A^*(P) \models \varphi$. (This basic form of circumscription has been generalized, for in practice, one needs to minimize the extension of a predicate, while allowing the extension of certain other predicates to vary.) From the point of view of applications, however, circumscription has a major computational shortcoming, which is due to the nature of second-order language in which circumscription is formulated. The problem is that SOL, contrary to FOL, lacks a complete inference procedure: the price one pays for the greater expressive power of second-order logic is that there are no complete axiomatizations, as we have for FOL. It follows that there is no way to list, in an effective manner, all SOL validities, and hence to determine whether $A(P) \mid\!\sim \varphi$.

Another non-monotonic formalism inspired by the intuition of minimization of abnormalities is *non-monotonic inheritance*. Whenever we have a taxonomically organized body of knowledge, we presuppose that subclasses inherit properties from their superclasses: dogs have lungs because they are mammals, and mammals have lungs. However, there can be exceptions, which can interact in complex ways. To use an example already introduced, mammals, by and large, don't fly; since bats are mammals, in the absence of any information to the contrary, we are justified in inferring that bats do not fly. But then we learn that bats are exceptional mammals, in that they do fly: the conclusion that they don't fly is retracted, and the conclusion that they fly is drawn instead. Things can be more complicated still, for in turn, as we have seen, baby bats are exceptional bats, in that they do not fly (does that make them unexceptional mammals?). Here we have potentially conflicting inferences. When we infer that Stellaluna, being a baby bat, does not fly, we are resolving all these potential conflicts based on a *specificity* principle: more

specific information overrides more generic information.

Non-monotonic inheritance networks were developed for the purpose of capturing taxonomic examples such as the above. Such networks are collections of nodes and directed ("IS-A") links representing taxonomic information. When exceptions are allowed, the network is interpreted *defeasibly*. The following figure gives a network representing this state of affair:

stellaluna diagram

In such a network, links of the form $A \rightarrow B$, represent the fact that, typically and for the most part, A's are B's, and that therefore information about A's is more specific than information about B's. More specific information overrides more generic information. Research on non-monotonic inheritance focuses on the different ways in which one can make this idea precise.

The main issue in defeasible inheritance is to characterize the set of assertions that are supported by a given network. It is of course not enough to devise a representational formalism, one also needs to specify how the formalism is to be interpreted. Such a characterization is accomplished through the notion of *extension* of a given network. There are two competing characterizations of extension for this kind of networks, one that follows the credulous strategy and one that follows the skeptical one. Both proceed by first defining the *degree* of path through the network as the length of the longest sequence of links connecting its endpoints; extensions are then constructed by considering paths in ascending order of their degrees. We are not going to review the details, since many of the same issues arise in connection with default logic (which is treated to greater length below), but Horty (1994) provides an extensive survey. It is worth mentioning that since the notion of degree makes sense only in the case of acyclic networks, special issues arise when networks contain cycles (see Antonelli (1997) for a treatment of inheritance on cyclic networks).

Although the language of non-monotonic networks is expressively limited by design (in that only links of the form "IS-A" can be represented in a natural fashion), such networks provide an extremely useful setting in which to test and hone one's intuitions and methods for handling defeasible information. Such intuitions and methods are then applied to more expressive formalisms. Among the latter is Reiter's *Default Logic*, perhaps the most flexible among non-monotonic frameworks.

In Default Logic, the main representational tool is that of a *default rule*, or simply a *default*. A default is a *defeasible inference rule* of the form

$$\frac{\gamma : \theta}{\tau}$$

(where γ, θ, τ are sentences in a given language, respectively called the pre-requisite, the justification

and the conclusion of the default). The interpretation of the default is that if γ is known, and there is no evidence that θ might be false, then τ can be inferred.

As is clear, application of the rule requires that a consistency condition be satisfied. What makes meeting the condition complicated is the fact that rules can interact in complex ways. In particular, it is possible that application of some rule might cause the consistency condition to fail for some, not necessarily distinct, rule. For instance, if θ is $\neg\tau$ then application of the rule is in a sense self-defeating, in that application of the rule itself causes the consistency condition to fail.

Reiter's default logic uses the notion of an *extension* to make precise the idea that the consistency condition has to be met both before and after the rule is applied. Given a set Γ of defaults, an extension for Γ represents a set of inferences that can be *reasonably* and *consistently* drawn using defaults from Γ. Such inferences are those that are warranted on the basis of a maximal set of defaults whose consistency condition is met both before and after their being triggered.

More in particular (and in typical circular fashion), an extension for Γ is a maximal subset Δ of Γ the conclusions of whose defaults both imply all the pre-requisites of defaults in Γ and are consistent with all the justifications of defaults in Γ. This definition can be made precise as follows. By a *default theory* we mean a pair (W,Δ), where Δ is a (finite) set of defaults, and W is a set of sentences (a world description). The idea is that W represents the strict or background information, whereas Δ specifies the defeasible information. Given a pair (T_1,T_2) of sets of sentences, a default such as the above is *triggered* by (T_1,T_2) if and only if $T_1 \models \gamma$ and it's not the case that $T_2 \models \neg\theta$ (i.e., θ is consistent with T_2). (Notice how this definition is built "on top" of $\models$: we could, conceivably, employ a different relation here.)

Finally we say that a set of sentences E is an *extension* for a default theory (W,Δ) if and only if

$$E = E_0 \cup E_1 \cup \ldots \cup E_n \cup \ldots ,$$

where: $E_0 = W$, and

$$E_{n+1} = E_n \cup \{ \tau : (\gamma : \theta) / \tau \in \Delta \text{ is triggered by } (E_n, E) \}.$$

It is important to notice the occurrence of the limit E in the definition of E_{n+1}): the condition above is not a garden-variety recursive defintion, but a truly circular characterization of extensions.

This circularity can be made explicit by giving an equivalent definition of extension as solutions of fixpoint equations. Given a default theory, let **S** be an operator defined on set of sentences such that for any set S of sentences, $\mathbf{S}(S)$ is the smallest set containing W, deductively closed (i.e., such that if $\mathbf{S}(S) \models \varphi$ then $\varphi \in \mathbf{S}(S)$), and such that if a default with consequent τ is triggered by (S,S) then $\tau \in \mathbf{S}(S)$. Then one can show that E is an extension for (W,Δ) if and only if E is a fixed point of **S**, i.e., if $\mathbf{S}(E) = E$.

For any given default theory, extensions need not exist, and even when they exist, they need not be unique. Let us consider a couple of examples. Our first example is a default theory that has no extension: let *W* contain the sentence γ let Δ comprise the single default

$$\frac{\gamma : \theta}{\neg\theta}$$

If *E* were an extension, then the default above would have to be either triggered or not triggered by it, and either case is impossible. If the default were triggered, then the consistency condition would fail, and if if were not triggered then the consistency condition would hold, and hence the default would have to be triggered by maximality of extensions.

Let us now consider an example of a default theory with multiple extensions. As before, let *W* contain the sentence γ, and suppose Δ comprises the following two defaults

$$\frac{\gamma : \theta}{\neg\tau}$$

and

$$\frac{\gamma : \tau}{\neg\theta}$$

This theory has exactly two extensions, one in which the first default is triggered and one in which the second one is. It is easy to see that at least a default has to be triggered in any extension, and that both defaults cannot be triggered by the same extension.

These example are enough to bring out a number of features. First, it should be noted that neither one of the two characterizations of default logic given above gives us a way to "construct" extension by means of anything resembling an iterative process. Essentially, one has to "guess" a set of sentences *E*, and then verify that it satisfies the definition of an extension.

Further, the fact that default theories can have zero, one, or more extensions raises the issues of what inferences one is warranted in drawing from a given default theory. The problem can be presented as follows: given a default theory (W,Δ), what sentences can be regarded as *defeasible consequences* of the theory? At first sight, there are several options available.

One option is to take the union of the extensions of the theory, and consider a sentence φ a consequence

of a given default theory if and only if φ belongs to *any* extension of the theory. But this option is immediately ruled out, in that it leads to endorsing contradictory conclusion, as in the second example above. It is widely believed that any viable notion of defeasible consequence for default logic must have the property that the set

$$\{\varphi : (W,\Delta) \mid\!\sim \varphi \}$$

must be consistent whenever W is. Once this option is ruled out, only two alternatives are left:

The first alternative, known as the "credulous" or "bold" strategy, is to pick an extension E for the theory, and say that φ is a defeasible consequence if and only if $\varphi \in E$. The second alternative, known as the "skeptical" or "cautious" strategy, is to endorse a conclusion φ if and only if φ is contained in *every* extension of the theory.

Both the credulous and the skeptical strategy have problems. The problem with the credulous strategy is that the choice of E is arbitrary: with the notion of extension introduced by Reiter, extensions are *orthogonal*: of any two distinct extensions, neither one contains the other. Hence, there seems to be no principled way to pick an extension over any other one. This has led a number of researcher to endorse the skeptical strategy as a viable approach to the problem of defeasible consequence. But as showed by Makinson, skeptical consequence, as based on Reiter's notion of extension, fails to be cautiously monotonic. To see this, consider the default theory $(W\Delta)$, where W is empty, and Δ comprises the following two defaults:

$$\frac{:\theta}{\theta}$$

and

$$\frac{\theta \vee \gamma : \neg\theta}{\neg\theta}$$

This theory has only one extension, coinciding with the deductive closure of $\{\theta\}$. Hence, if we define defeasible consequence by putting $(W,\Delta) \mid\!\sim \varphi$ if and only if φ belongs to every extension of (W,Δ), we have $(W,\Delta) \mid\!\sim \theta$, as well as $(W,\Delta) \mid\!\sim \theta \vee \gamma$ (by the deductive closure of extensions).

Now consider the theory with Δ as before, but with W containing the sentence $\theta \vee \gamma$. This theory has two extensions: one the same as before, but also another one coinciding with the deductive closure of $\{\neg\theta\}$, and hence not containing θ. It follows that the intersection of the extensions no longer contains θ, so that $(\{\theta \vee \gamma\}\ \Delta) \mid\!\sim \theta$ now *fails*, against cautious monotony. (Notice that the same example establishes a

counter-example for Cut for the credulous strategy, when we pick the extension of $(\{\theta \vee \gamma\}, \Delta)$ that contains $\neg\theta$.)

It is clear that the issue of how to define a non-monotonic consequence relation for default logic is intertwined with the way that *conflicts* are handled. The problem of course is that in this case neither the skeptical nor the credulous strategy yield an adequate relation of defeasible consequence. In Antonelli (1999) a notion of *general extension* for default logic is introduced, showing that this notion yields a well-behaved relation of defeasible consequence that satisfies all four requirements of Supraclassicality, Reflexivity, Cut, and Cautious Monotony.

A different set of issues arises in connection with the behavior of default logic from the point of view of computation. For a given semi-decidable set Γ of sentences, the set of all φ that are a consequence of Γ in FOL is itself semi-decidable (see "Computability", this Encyclopedia). In the case of default logic, to formulate the corresponding problem one extends (in the obvious way) the notion of (semi-)decidability to sets of defaults. The problem, then, is to decide, given a default theory (W, Δ) and a sentence φ whether $(W, \Delta) \mid\!\sim \varphi$, where $\mid\!\sim$ is defined, say, skeptically. Such a problem is not even semi-decidable, the essential reason being that in general, in order to determine whether a default is triggered by a pair of sets of sentences, one has to perform a consistency check, and such checks are not computable.

But the consistency checks are not the only source of complexity in default logic. For instance, we could restrict our language to conjunctions of atomic sentences and their negations (making consistency checks feasible). Even so, the problem of determining whether a given default theory has an extension would still be highly intractable (NP-complete, to be precise, as shown by Kautz & Selman (1991)}), seemingly because the problem requires checking all possible sequences of firings of defaults

Default logic is intimately connected with certain *modal* approaches to non-monotonic reasoning, which belong to the family of *autoepistemic logics*. Modal logics in general have proved to be one of the most flexible tools for modelling all sorts of dynamic processes and their complex interactions (see the entry "modal logic", this Encyclopedia). Beside the applications in knowledge representation, which we are going to treat below, there are modal frameworks, known as *dynamic logics*, that play a crucial role, for instance, in the modelling of serial or parallel computation. The basic idea of modal logic is that the language is interpreted with respect to a given set of *states*, and that sentences are evaluated relative to one of these states. What these states are taken to represent depends on the particular application under consideration (they could be epistemic states, or states in the evolution of a dynamical system, etc.), but the important thing is that there are *transitions* (of one or more different kinds) between states.

In the case of one transition that is both *transitive* (i.e., such that if $a \rightarrow b$ and $b \rightarrow c$ then $a \rightarrow c$) and *euclidean* (if $a \rightarrow b$ and $a \rightarrow c$ then $b \rightarrow c$), the resulting modal system is referred to as K45. Associated with each kind of state transition there is a corresponding modality in the language, usually represented as a box $\Box$. A sentence of the form $\Box A$ is true at a state s if and only if A is true at every state s' reachable from s by the kind of transition associated with $\Box$ (see Chellas (1980) for a comprehensive introduction to modal logic).

In autoepistemic logic, the states involved are epistemic states of the agent (or agents). The intuition underlying autoepistemic logic is that we can sometimes draw inferences concerning the state of the world using information concerning our own knowledge or ignorance. For instance, I can conclude that I do not have a sister given that if I did I would probably know about it, and nothing to that effect is present in my "knowledge base". But such a conclusion is defeasible, since there is always the possibility of learning new facts. In order to make these intuitions precise, consider a modal language in which the necessity operator $\Box$ is interpreted as "it is known that". As in default logic or defeasible inheritance, the central notion in autoepistemic logic is that of an *extension* of a theory *S*, i.e., a consistent and self-supporting sets of beliefs that can reasonably be entertained on the basis of *S*. Given a set *S* of sentences, let S_0 be the subset of *S* composed of those sentences containing no occurrences of $\Box$; further, let the *positive introspective closure* PIC(S_0) of S_0 be the set

$$\{\Box\varphi : \varphi \in S_0\},$$

and the *negative introspective closure* NIC(S_0) of S_0 the set

$$\{\neg\Box\varphi : \varphi \notin S_0\}.$$

The set PIC(S_0) is called the introspective closure because it explicitly contains positive information about the agent’s epistemic status: PIC(S_0) expresses what is known (similarly, NIC(S_0) contains negative information about the agent’s epistemic status, stating explicitly what is not known).

With these notions in place, we define an extension for *S* to be a set *T* of sentences such that:

$$T = \{ \varphi : \varphi \text{ follows (in K45) from } S \cup \text{PIC}(T_0) \cup \text{NIC}(T_0) \}$$

Autoepistemic logic provides a rich language, with interesting mathematical properties and connections to other non-monotonic formalisms. It is faithfully intertranslatable with Reiter’s version of default logic, and provides a defeasible framework with well-understood modal properties.

Conclusion

There are three major issues connected with the development of logical frameworks that can adequately represent defeasible reasoning: (*i*) material adequacy; (*ii*) formal properties; and (*iii*) complexity. Material adequacy concerns the question of how broad a range of examples is captured by the framework, and the extent to which the framework can do justice to our intutions on the subject (at least the most entrenched ones). The question of formal properties has to do with the degree to which the framework allows for a relation of logical consequence that satisfies the above mentioned conditions of Supraclassicality, Reflexivity, Cut, and Cautious Monotony. The third set of issues has to do with computational

complexity of the most basic questions concerning the framework.

There is a potential tension between (*i*) and (ii): the desire to capture a broad range of intuitions can lead to *ad hoc* solutions that can sometimes undermine the desirable formal properties of the framework. In general, the development of non-monotonic logics and related formalisms has been driven, since its inception, by consideration (*i*) and has relied on a rich and well-chosen array of examples. Of course, there is some question as to whether any single framework can aspire to be universal in this respect.

More recently, researchers have started paying attention to consideration (*ii*), looking at the extent to which non-monotonic logics have generated well-behaved relations of logical consequence. As Makinson (1994) points out, practitioners of the field have encountered mixed success. In particular, one abstract property, Cautious Monotony, appears at the same time to be crucial and elusive for many of the frameworks to be found in the literature. This is a fact that is perhaps to be traced back, at least in part, to the above-mentioned tension between the requirement of material adequacy and the need to generate a well-behaved consequence relation. The complexity issue appears to be the most difficult among the ones that have been singled out. Non-monotonic logics appear to be stubbornly intractable with respect to the corresponding problem for classical logic. This is clear in the case of default logic, given the ubiquitous consistency checks. But beside consistency checks, there are other, often overlooked, sources of complexity that are purely combinatorial. Other forms of nonmonotonic reasoning, beside default logic, are far from immune from these combinatorial roots of intractability. Although some important work has been done trying to make various non-monotonic formalism more tractable, this is perhaps the problem on which progress has been slowest in coming.

First-order Model Theory

First-order model theory, also known as classical model theory, is a branch of mathematics that deals with the relationships between descriptions in first-order languages and the structures that satisfy these descriptions. From one point of view, this is a vibrant area of mathematical research that brings logical methods (in particular the theory of definition) to bear on deep problems of classical mathematics. From another point of view, first-order model theory is the paradigm for the rest of model theory; it is the area in which many of the broader ideas of model theory were first worked out.

1. First-order languages and structures

Mathematical model theory carries a heavy load of notation, and HTML is not the best container for it. In what follows, syntactic objects (languages, theories, sentences) are generally written in roman or greek letters (for example L, T, φ), and set-theoretic objects such as structures and their elements are written in italic (*A*, *a*). Two exceptions are that variables are italic (*x*, *y*) and that sequences of elements are written with lower case roman letters (a, b).

We recall and refine some definitions from the entries on classical logic and model theory. A *signature* is a set of individual constants, predicate symbols and function symbols; each of the predicate symbols and function symbols has an *arity* (for example it is binary if its arity is 2). Each signature K gives rise to a first-order language, by building up formulas from the symbols in the signature together with logical symbols (including =) and punctuation.

If K is a signature, then a *structure of signature* K, say *A*, consists of the following items:

1. A set called the *domain* of *A* and written dom(*A*); it is usually assumed to be nonempty;
2. for each individual constant *c* in K, an element c^A of dom(*A*);
3. for each predicate symbol *P* of arity *n*, an *n*-ary relation P^A on dom(*A*);
4. for each function symbol *F* of arity *n*, an *n*-ary function F^A from dom(*A*) to dom(*A*).

The *elements* of *A* are the elements of dom(*A*). Likewise the *cardinality* or *power* of *A* is the cardinality of its domain. Since we can recover the signature K from the first-order language L that it generates, we can and will refer to structures of signature K as L-*structures*. We think of *c* as a name for the element c^A in the structure *A*, and likewise with the other symbols.

For example the field of real numbers forms a structure ***R*** whose elements are the real numbers, with signature consisting of the individual constant 0 to name the number zero, a 1-ary function symbol - for minus, and two 2-ary function symbols + and . for plus and times. At first sight we can't add a symbol to express 1/*x*, since all the named functions have to be defined on the whole domain of the structure, and there is no such real number as 1/0. But on second thoughts this is not a serious problem; any competent mathematician puts the condition '*x* is not zero' before dividing by *x*, and so it never matters what the value of 1/0 is, and we can harmlessly take it to be 42. But most model theorists are uncomfortable with any kind of division by zero, so they stick with plus, times and minus.

If L is the first-order language of signature K, then Tarski's model-theoretic truth definition tells us when a sentence of L is true in *A*, and when an assignment of elements of *A* to variables satisfies a formula of L in *A*. Instead of talking of assignments satisfying a formula, model theorists often speak of the set of *n*-tuples of elements of *A* that is *defined* by a formula $\varphi(v_1,...,v_n)$; the connection is that an *n*-tuple $(a_1,...,a_n)$ is in the defined set if and only if the assignment taking each v_i to a_i satisfies the formula.

If φ is a sentence, we write

$$A \models \varphi$$

to mean that φ is true in *A*. If $\varphi(v_1,...,v_n)$ is a formula with free variables as shown, we write

$$A \models \varphi[\mathrm{a}]$$

to mean that the *n*-tuple a is in the set defined by φ. (The entry on classical logic uses the notation '$A,s \models \varphi$', where *s* is any assignment to all the variables of L that assigns to each variable v_i free in φ the *i*-th element in the *n*-tuple a.)

Two L-structures that are models of exactly the same sentences of L are said to be *elementarily equivalent*. Elementary equivalence is an equivalence relation on the class of all L-structures. The set of all the sentences of L that are true in the L-structure *A* is called the *complete theory* of *A*, in symbols Th(*A*). A theory that is Th(*A*) for some structure *A* is said to be *complete*. (By the completeness theorem for first-order logic, for which see the entry on classical logic, a theory is complete if and only if it is maximal syntactically consistent.) The two structures *A* and *B* are elementarily equivalent if and only if Th(*A*) = Th(*B*).

To continue the example of the field ***R*** of real numbers: It is often not at all obvious whether two given structures are or are not elementarily equivalent. One of the greatest achievements of the pre-history of model theory was Tarski's description in 1930 of Th(***R***) (which he published in full only after the war; see his book in the Bibliography below). This description implied among other things that the structures elementarily equivalent to ***R*** are exactly the real-closed fields, a class of fields which was already known to the algebraists in its own right.

When mathematicians introduce a class of structures, they like to define what they count as the basic maps between these structures. The basic maps between structures of the same signature K are called *homomorphisms*, defined as follows. A *homomorphism from structure A to structure B* is a function *f* from dom(*A*) to dom(*B*) with the property that for every atomic formula $\varphi(v_1,...,v_n)$ and any *n*-tuple a = $(a_1,...,a_n)$ of elements of *A*,

$$A \models \varphi[\mathrm{a}] \Rightarrow B \models \varphi[\mathrm{b}]$$

where b is $(f(a_1),...,f(a_n))$. If we have '⇔' in place of ' ⇒ ' in the quoted condition, we say that *f* is an *embedding* of *A* into *B*. Since the language includes =, an embedding of *A* into *B* is always one-to-one, though it need not be onto the domain of *B*. If it is onto, then the inverse map from dom(*B*) to dom(*A*) is also a homomorphism, and both the embedding and its inverse are said to be *isomorphisms*. We say that two structures are *isomorphic* if there is an isomorphism from one to the other. Isomorphism is an equivalence relation on the class of all structures of a fixed signature K. If two structures are isomorphic then they share all model-theoretic properties; in particular they are elementarily equivalent.

If *A* and *B* are structures of signature K with dom(*A*) a subset of dom(*B*), and the interpretations in *A* of the symbols in K are just the restrictions of their interpretations in *B*, then we say that *A* is a *substructure* of *B* and conversely *B* is an *extension* of *A*. If moreover *B* has some elements that are not in *A*, we say that *A* is a *proper substructure* of *B* and *B* is an *proper extension* of *A*. If *B* is a structure and *X* is a nonempty subset of dom(*B*), then there is a unique smallest substructure of *B* whose domain contains all of *X*. It is known as the *substructure of B* generated by X, and we find it by first adding to *X* all the elements c^B where *c* are individual constants, and then closing off under the functions F^B where *F* are function symbols.

For example the substructure of the field ***R*** generated by the number 1 consists of 1, 0 (since it is named by the constant 0), 1+1, 1+1+1 etc., -1, -2 etc., in other words the ring of integers. (There is no need to close off under multiplication too, since the set of integers is already closed under multiplication.) If we had included a symbol for $1/x$ too, the substructure generated by 1 would have been the field of rational numbers. So the notion of substructure is sensitive to the choice of signature.

2. Elementary maps

Let L be a first-order language and let *A* and *B* be L-structures. Suppose *e* is a function which takes some elements of *A* to elements of *B*. We say that *e* is an *elementary map* if whenever a sequence of elements $a_1, ..., a_n$ in the domain of *e* satisfy a formula $\varphi(x_1,...,x_n)$ of L in *A*, their images under *e* satisfy the same formula in *B*; in symbols

$$A \models \varphi(a_1,...,a_n) \Rightarrow B \models \varphi(e(a_1),...,e(a_n)).$$

We say that *e* is an *elementary embedding* of *A* into *B* if *e* is an elementary map and its domain is the whole domain of *A*. As the name implies, elementary embeddings are always embeddings.

If there is an elementary embedding from *A* to *B* then *A* and *B* are elementarily equivalent. On the other hand an embedding between elementarily equivalent structures, or even between isomorphic structures, need not be elementary. (For example, writing ***Z*** for the abelian group of the integers with signature consisting of 0 and +, the embedding from ***Z*** to ***Z*** that takes each integer *n* to 2*n* is an embedding, and of course ***Z*** is isomorphic to itself; but this embedding is not elementary, since 1 satisfies the formula $\neg\exists y(y + y = v_1)$, but 2 doesn't.)

We say that *A* is an *elementary substructure* of *B*, and *B* is an *elementary extension* of *A*, if *A* is a substructure of *B* and the inclusion map is an elementary embedding. It's immediate from the definitions that an elementary extension of an elementary extension of *A* is again an elementary extension of *A*.

Elementary embeddings are natural maps to consider within first-order model theory. Around 1950 Abraham Robinson was impressed that maps between algebraic structures in general seem hardly ever to be elementary, whereas some important maps (such as embeddings between two algebraically closed fields, or between two real-closed fields) turn out to be elementary. He was also surprised to find that this fact about algebraically closed fields is another way of stating a celebrated theorem called the Hilbert Nullstellensatz. These observations of Robinson have had a huge effect on the development of model theory. In Robinson's terminology, a first-order theory is *model-complete* if every embedding between models of the theory is elementary. This notion has found many uses, and it often appears in applications of model theory in algebra.

Elementary embeddings have a number of properties that make them useful. We have space for four.

> **The downward Loewenheim-Skolem theorem**:
> Suppose L is a first-order language which has κ formulas, *A* is an L-structure and λ is a cardinal which is at least κ but less than the cardinality of *A*. Suppose also that *X* is a set of at most λ elements of *A*. Then *A* has an elementary substructure which has cardinality exactly λ and contains all the elements in *X*.

There is a proof of this in the entry on classical logic, using Skolem hulls. Note that λ must be infinite since every first-order language has infinitely many formulas.

> **The elementary chain theorem**:
> Suppose that L is a first-order language and A_0, A_1, ... is a sequence (of any length) of L-structures such that any structure in the sequence is an elementary substructure of all the later structures in the sequence. Then there is a unique smallest L-structure *B* which contains all the structures in the sequence as substructures; this structure *B* is an elementary extension of all the structures in the sequence.

> **The elementary amalgamation theorem**:
> Suppose L is a first-order language, *A* is an L-structure and *B*, *C* are two elementary extensions of *A*. Then there are an elementary extension *D* of *B* and an elementary embedding *e* of *C* into *D* such that (i) for each element *a* of *A*, *e(a)* = *a*, and (ii) if *c* is an element of *C* but not of *A*, then *e(c)* is not in *B*.

The latter is a consequence of the compactness theorem in the next section.

> **The upward Loewenheim-Skolem theorem**:
> Suppose L is a first-order language which has κ formulas, *A* is an L-structure whose cardinality is an infinite cardinal μ, and λ is a cardinal which is at least as great as both κ and μ. Then *A* has an elementary extension whose cardinality is λ.

There is a proof of this in the entry on classical logic. The name of the theorem is a little unfortunate, since the theorem was first proved by Tarski, and Skolem didn't even believe it (because he didn't believe in uncountable cardinals).

There is another proof using the elementary amalgamation theorem and the elementary chain theorem. The compactness theorem and the diagram lemma (see below) allow us to prove that *A* has a proper elementary extension A'. Now use A' and again A' for the structures *B* and *C* in the elementary amalgamation theorem. Then *D* as in the theorem is an elementary extension of *A*, and by (ii) in the theorem, it must contain elements that are not in *A*, so that it is a proper elementary extension. Repeat to get a proper elementary extension of *D*, and so on until you have an infinite elementary chain. Use the elementary chain theorem to find an elementary extension of *A* that sits on top of this chain. Keep repeating these moves until you have an elementary extension of *A* that has cardinality at least λ. Then if

necessary use the downward Loewenheim-Skolem theorem to pull the cardinality down to exactly λ. This kind of argument is very common in first-order model theory.

3. Five grand theorems

The five theorems reported in this section are in some sense the pillars of classical model theory. All of them are theorems about first-order model theory. A great deal of the work done in the third quarter of the twentieth century was devoted to working out the consequences of these theorems within first-order model theory, and the extent to which similar theorems hold for languages that are not first-order.

3.1 The compactness theorem

> If T is a first-order theory, and every finite subset of T has a model, then T has a model.

There is a proof of this theorem in the entry on classical logic. The theorem has several useful paraphrases. For example it is equivalent to the following statement:

> Suppose T is a first-order theory and φ is a first-order sentence. If T $\models \varphi$ then there is a finite subset U of T such that U $\models \varphi$.

(See the entry Model Theory for the notion $\models$ of model-theoretic consequence. To derive the second statement from the first, note that 'T $\models \varphi$' is true if and only if there is no model of the theory T $\cup$ {$\neg \varphi$}.)

Anatolii Mal'tsev first gave the compactness theorem in 1938 (for first-order logic of any signature), and used it in 1940/1 to prove several theorems about groups; this seems to have been the first application of model theory within classical mathematics. Leon Henkin rediscovered the theorem a few years later and gave some further applications. The theorem fails badly for nearly all infinitary languages.

3.2 The diagram lemma

If *A* is an L-structure, then we form the *diagram* of *A* as follows. First add to L a supply of new individual constants to serve as names for all the elements of *A*. (This illustrates how in first-order model theory we easily find ourselves using uncountable signatures. The 'symbols' in these signatures are abstract set-theoretic objects, not marks on a page.) Then using L and these new constants, the *diagram* of *A* is the set of all the atomic sentences and negations of atomic sentences that are true in *A*.

> If B' is a model of the diagram of *A*, and *B* is B' with the new constants removed from the signature, then there is an embedding of *A* into *B*.

Namely, if an element of *A* is named by a new constant *c*, then map that element to the element of B' named *c*. A variant of this lemma is used in the proof of the elementary amalgamation theorem.

3.3 The Lyndon interpolation theorem

This theorem may have the longest pedigree of any theorem of model theory, since it generalises the Laws of Distribution for syllogisms, which go back at least to the early Renaissance. The theorem is easiest to state if we assume that our first-order languages have symbols $\wedge$, $\forall$ and $\neg$, but not $\rightarrow$ or $\leftrightarrow$. Then an occurrence of a predicate symbol R in a formula φ is said to be *positive* (resp. *negative*) if it lies within the scope of an even (resp. odd) number of occurrences of $\neg$.

> Suppose L and M are first-order languages, L $\cup$ M is the smallest first-order language containing both L and M, and L $\cap$ M is the language consisting of all the formulas which are in both L and M. Suppose T is a theory in L, U is a theory in M, and no (L $\cup$ M)-structure is both a model of T and a model of U. Then there is a sentence φ of L $\cap$ M which is true in all models of T and false in all models of U. (This sentence φ is called the *interpolant*.) Moreover every predicate symbol with a positive occurrence in φ has a positive occurrence in some sentence of T and a negative occurrence in some sentence of U, and conversely every predicate symbol with a negative occurrence in φ has a negative occurrence in some sentence of T and a positive occurrence in some sentence of U.

There are several proofs of this theorem, and not all of them are model-theoretic. Without the last sentence, the theorem is known as Craig's interpolation theorem, since William Craig proved this version a few years before Roger Lyndon found the full statement in 1959. As Craig noted at the time, his interpolation theorem gives a neat proof of Evert Beth's definability theorem, which runs as follows.

Suppose that L is a first-order language and M is the first-order language got by adding to L a new predicate symbol R. Suppose also that T is a theory in M. We say that T *implicitly defines* R if it is false that there are two M-structures which are models of T, have the same elements and interpret all the symbols of L in the same way but interpret the symbol R differently. We say that T *defines* R *explicitly* if there is a formula $\varphi(x_1,...,x_n)$ of L such that in every model of T, the formulas φ and $R(x_1,...,x_n)$ are satisfied by exactly the same *n*-tuples $(a_1,...,a_n)$ of elements. It is easy to see that if T defines R explicitly then it defines R implicitly. (This fact is known as *Padoa's method*; Padoa used the failure of implicit definability as a way of proving the failure of explicit definability.) Beth's theorem is the converse:

> Suppose that L, M, R and T are as above. If T defines R implicitly then T defines R explicitly.

3.4 The omitting types theorem

> Suppose L is a first-order language which has countably many formulas. Suppose T is a complete theory in L, and Φ is a set of formulas of L which all have the free variable *x*. Finally suppose that every model of T contains an element which satisfies all the formulas in Φ. Then there is a formula $\psi(x)$ of L such that in every model of T there is an element satisfying ψ, and every element that satisfies ψ in any model of T also satisfies all the formulas in Φ. (In other words, there is a finite reason why the 'type' Φ can't be 'omitted' in any model of T.)

This theorem, which goes back to the mid 1950s, very definitely depends on the language being first-order and countable. It has several useful generalisations, for example *model-theoretic forcing*, which is an analogue of the forcing construction in set theory. In fact the games used for model-theoretic forcing (see the entry on logic and games) can be adapted to prove the omitting types theorem too. There are similar but more complicated theorems for uncountable first-order languages; some of these can be paraphrased as omitting types theorems for infinitary languages.

3.5 The initial model theorem

A quantifier-free formula is said to be a *Horn formula* (after Alfred Horn) if it has one of the three forms

- ψ,
- $\varphi_1 \wedge \ldots \wedge \varphi_n \rightarrow \psi$,
- $\neg(\varphi_1 \wedge \ldots \wedge \varphi_n)$,

where the formulas $\varphi_1, \ldots, \varphi_n, \psi$ are all atomic. A *universal Horn sentence* (also known to the computer scientists as a *Horn clause*) is a sentence that consists of universal quantifiers followed by a quantifier-free Horn formula; it is said to be *strict* if no negation sign occurs in it (i.e. if it doesn't come from a quantifier-free Horn formula of the third kind).

> Let T be a theory consisting of strict universal Horn sentences. Then T has a model *A* with the property that for every model *B* of T there is a unique homomorphism from *A* to *B*. (Such a model *A* is called an *initial model* of T. It is unique up to isomorphism.)

This theorem is a generalisation, due to Mal'tsev, of a group-theoretic construction called *construction by generators and relations*. It is the main idea behind *algebraic specification*, which is one approach to the specification of systems in computer science. The required behaviour of the system is written down as a set of strict universal Horn sentences, and then the initial model of these sentences is an abstract version of the required system.

4. Three useful constructions

A construction is a procedure for building a structure. We have already seen several constructions in the theorems above: for example the omitting types construction and the initial model construction. Here are three more.

4.1 Products and reduced products

If *A* and *B* are L-structures, we form their *product* $C = A \times B$ as follows. The elements of *C* are the ordered pairs (*a*,*b*) where *a* is an element of *A* and *b* is an element of *B*. The predicate symbols are interpreted 'pointwise', i.e. so that for example

> *(a,b)* is in P^C if and only if *a* is in P^A and *b* is in P^B.

The structures *A* and *B* are called the *factors* of $A \times B$. In the same way we can form products of any number of structures. If all the factors of a product are the same structure *A*, the product is called a *power* of *A*. A theorem called the *Feferman-Vaught theorem* tells us how to work out the complete theory of the product from the complete theories of its factors.

This construction has some variants. We can define an equivalence relation on the domain of a product *C*, and then take a structure *D* whose elements are the equivalence classes; the predicate symbols are interpreted so as to make the natural map from dom(*C*) to dom(*D*) a homomorphism. In this case the structure *D* is called a *reduced product* of the factors of *C*. It is a *reduced power* of *A* if all the factors are equal to *A*; in this case the *diagonal map* from *A* to *D* is the one got by taking each element *a* to the equivalence class of the element *(a,a,...)*.

Suppose we use a set *I* to index the factors in a product *C*. An *ultrafilter* over *I* is a set *U* of subsets of *I* with the properties

- if sets *X* and *Y* are in *U* then so is their intersection $X \cap Y$;
- if *X* is in *U* and $X \subseteq Y \subseteq I$ then *Y* is in *U*;
- for each subset *X* of *I*, exactly one of *X* and its complement $I \setminus X$ is in *U*.

If we have an ultrafilter *U* over *I*, then we can construct a reduced product from *C* by making two elements of *C* equivalent if and only if the set of indices at which they are equal is a set in the ultrafilter *U*. This is indeed an equivalence relation on the domain of *C*, and the resulting reduced product is called an *ultraproduct* of the factors of *C*. If *C* is a power of *A* then this ultraproduct is called an *ultrapower* of *A*, and it is sometimes written *U*-prod *A*. A theorem called *Los's theorem* describes what sentences are true in an ultraproduct. Its most useful consequence is the following:

> If *U* is an ultrafilter then the diagonal map from *A* to *U*-prod *A* is an elementary

embedding.

If the ultrafilter *U* is *nonprincipal*, i.e. contains no finite sets, then the diagonal map is not onto the domain of *U*-prod *A*, and in fact *U*-prod *A* is generally much larger than *A*. So we have a way of constructing large elementary extensions. The axiom of choice guarantees that every infinite set has many nonprincipal ultrafilters over it. Ultrapowers are an essential tool for handling large cardinals in set theory (see the entry on set theory).

A remarkable (but in practice not terribly useful) theorem of Saharon Shelah tells us that a pair of structures *A* and *B* are elementarily equivalent if and only if they have ultrapowers that are isomorphic to each other.

4.2 Saturation

Suppose *A* is an L-structure, *X* is a set of elements of *A*, *B* is an elementary extension of *A* and *b*, *c* are two elements of *B*. Then *b* and *c* are said to have *the same type over X* if for every formula $\varphi(v_1,\ldots,v_{n+1})$ of L and every *n*-tuple d of elements of *X*,

$$B \models \varphi[b,\mathrm{d}] \Leftrightarrow B \models \varphi[c,\mathrm{d}].$$

We say that *A* is *saturated* if whenever *X* is a set of elements of *A*, of cardinality less than that of *A*, and *B* is any elementary extension of *A*, we always have that every element of *B* has the same type over *X* as some element already in *A*.

This rather heavy definition gives little clue how useful saturated structures are. If every structure had a saturated elementary extension, many of the results of model theory would be much easier to prove. Unfortunately the existence of saturated elementary extensions depends on features of the surrounding universe of sets. There are technical ways around this obstacle, for example using weakenings of the notion of saturation. We have two main ways of constructing saturated elementary extensions. One is by ultrapowers, using cleverly constructed ultrafilters. The other is by taking unions of elementary chains, generalising the proof we gave for the upward Loewenheim-Skolem theorem.

The existence of partially saturated elementary extensions of the field ***R*** of real numbers is the main technical fact behind Abraham Robinson's *nonstandard analysis*. See Section 4 of the entry on model theory for more information on this. Though model theory provided the first steps in nonstandard analysis, this branch of analysis rapidly became a subject in its own right, and its links with first-order model theory today are rather slim.

4.3 Ehrenfeucht-Mostowski models

Let A be an L-structure, X a set of elements of A and < a linear ordering of X (not necessarily definable by a first-order formula). We say that $(X,<)$ is an *indiscernible sequence* in A if for every natural number n, and all elements $a_1,...,a_n,b_1,...,b_n$ of A such that $a_1 < ... < a_n$ and $b_1 < ... < b_n$, the map taking each a_i to the corresponding b_i is an elementary map. If T is a theory with infinite models, then T has models that are the Skolem hulls (see the entry on classical logic) of indiscernible sequences. These models are known as *Ehrenfeucht-Mostowski models*, after the two Polish model theorists who first carried out this construction in the mid 1950s. These models tend to be the opposite of saturated; we can arrange that very few types over sets of elements are represented among their elements. Some important distinctions between different models of set theory can be expressed in terms of the indiscernible sequences within these models; see the entry on set theory.

5. Three successful programmes

Every healthy branch of mathematics needs a set of problems that form a serious challenge for its researchers. We close with a brief introduction to some of the research programmes that drove first-order model theory forwards in the second half of the twentieth century. There are other current programmes besides these; see for example the handbook edited by Yuri Ershov in the bibliography, which is about model theory when the structures are built recursively.

5.1. Categoricity and classification

In 1904 Oswald Veblen stole a term from Kant and described a theory as *categorical* if it has just one model up to isomorphism (i.e. it has a model and all its models are isomorphic to each other). The depressing news is that there are no categorical first-order theories with infinite models; we can see this at once from the upward Loewenheim-Skolem theorem. In fact if T is a first-order theory with infinite models, then the strongest kind of categoricity we can hope for in T is that for certain infinite cardinals κ, T has exactly one model of cardinality κ, up to isomorphism. This property of T is called κ-*categoricity*.

Now there is a heuristic principle that many people have used, though it seems to have no simple formulation. I suggest ‘Few is beautiful’. The principle says that if a first-order theory T constrains its models (of a particular cardinality) to be all similar to each other, this can only be because the models of T have few irregularities and asymmetries. So there should be a good structural description of these models. One should expect that they are ‘good structures’ from the point of view of classical mathematics. As a first step, one easily sees from the upward and downward Loewenheim-Skolem theorems that if T is κ-categorical for some κ at least as large as the number of formulas in the language of T, then T must be a complete theory. From now on, T is a complete theory with infinite models; and for simplicity we shall assume that the language of T is countable.

In 1954 Jerzy Los announced that he could only find three kinds of example of theories T that are κ-categorical. Namely:

- T is *totally categorical* if it is κ-categorical for every infinite cardinal κ. A typical example is the complete theory of an infinite-dimensional vector space over a finite field.
- T is *uncountably categorical* (but not totally categorical) if it is κ-categorical precisely when κ is uncountable. Essentially the only example that Los could find was the complete theory of an algebraically closed field; this is uncountably categorical by a well-known theorem of Steinitz.
- T is *countably categorical* (but not uncountably categorical) if it is κ-categorical precisely when κ is countable. A typical example is the complete theory of a dense linear ordering with no first or last element; this is countably categorical by a well-known theorem of Cantor.

Los asked whether there are any other possibilities besides these three. (Of course most complete theories are not κ-categorical for any κ.)

This question of Los was a tremendous stimulus to research, and it led to a classic paper of Michael Morley in 1965 which showed that Los's three possibilities are in fact the only ones. One central idea of Morley's analysis was that models of an uncountably categorical theory have the smallest possible number of types of element; this led directly to the branch of model theory called *stability theory*, which studies theories that have a limited number of element types. These theories have the remarkable property that every infinite indiscernible sequence in any of their models is indiscernible under any linear ordering whatever; so these sequences are a kind of generalisation of bases of vector spaces. Another idea implicit in Morley's work, but much clarified by later work of John Baldwin and Alistair Lachlan, was that in any model of an uncountably categorical theory there is a central core (called a *strongly minimal set*) which carries a dependence relation obeying similar laws to linear dependence in vector spaces. In terms of this dependence relation one can define a dimension for the model, and what remains of the model outside the core is so closely tied to the core that the dimension determines the model up to isomorphism.

Saharon Shelah developed Morley's ideas with tremendous resourcefulness and energy. His main aim was to stretch the 'Few is beautiful' idea by showing that there are clear dividing lines between kinds of theory T. On one side of a dividing line are theories with some good structural property that forces the number of nonisomorphic models of a given cardinality to be small. On the other side, every theory has (for example) two models of the same cardinality that are not isomorphic but are extremely hard to tell apart. Shelah coined the name *classification theory* for this research, though the name never caught on. The text of Lascar listed below is an elegant introduction to this whole programme, from Los to Shelah. Meanwhile Shelah himself has extended it far beyond first-order logic. Even in the first-order case, Shelah had to invent new set-theoretic techniques (such as proper forcing) to carry out his constructions.

5.2. Geometric model theory

Geometric model theory grew out of Michael Morley's 1965 paper, but in a different direction from Shelah's work (though today it makes regular use of technical tools developed by Shelah in his classification programme). Morley had shown that models of an uncountably categorical theory have structural properties that are interesting in their own right, regardless of the complete theory of the

structure; so it became the custom to talk of *uncountably categorical structures*, meaning models of uncountably categorical theories. (And likewise *totally categorical structures*.) Independently Boris Zil'ber in Siberia and Greg Cherlin in the United States noticed that any infinite group that is definable in an uncountably categorical structure must have many features in common with the algebraic groups studied by algebraic geometers. Zil'ber in particular showed that many methods from algebraic geometry generalise to the model-theoretic case. His secret weapon was Bezout's Theorem from geometry, which he used to guide him to solutions of very difficult model theoretic problems; for example his theorem that no totally categorical theory can be axiomatised by a finite number of axioms. (It was secret in the sense that it guided his intuition but never appeared explicitly in his results.) Zil'ber also noticed an important difference between the first and second of Los's examples above. Namely, in a vector space the subspaces (i.e. the subsets closed under linear dependence) form a modular lattice; but the algebraically closed subsets of an algebraically closed field form a lattice that is not modular.

Partly because of the difficulty of communications between Siberia and the West, these results of Zil'ber took some time to digest, and in part they had to be rediscovered in the West. But when the message did finally get through, the result was a new branch of model theory which has come to be known as *geometric model theory*. The programme is broadly to classify structures according to (a) what groups or fields are interpretable in them (in the sense sketched in the entry on model theory) and (b) whether or not the structures have 'modular geometries'; and then to use this classification to solve problems in model theory and geometry. Since the mid 1980s the leader of this research has been Ehud Hrushovski. In the early 1990s, using joint work with Zil'ber, Hrushovski gave a model-theoretic proof (the first complete proof to be found) of the geometric Mordell-Lang conjecture in all characteristics; this was a conjecture in classical diophantine geometry. The book edited by Bouscaren in the references below is devoted to Hrushovski's proof and the necessary background in model theory. Both (a) and (b) are fundamental to Hrushovski's argument.

5.3. O-minimality

Of the three programmes described here, this is the oldest, since it grew out of Tarski's description of the complete theory of the field of real numbers (which he proved by the method of quantifier elimination; see section 2.2 of the entry on Tarski's truth definitions). In the course of giving this description, Tarski had shown that every first-order formula $\varphi(x)$ in the relevant language, possibly with parameters, is satisfied by exactly the same assignments as some boolean combination of formulas of the form $x < s$ or $t < x$ where s, t are constant terms naming parameters. Another way of saying this is that

> Every set of elements definable by a first-order formula is a finite union of open intervals with named endpoints, together with some finite set of elements.

A linearly ordered structure with this property is said to be *o-minimal*. (The idea of the name is that o-minimality is an analogue of Morley's 'strong minimality', in a form that makes sense for structures that carry a linear ordering, whence 'o-' for ordering.)

In 1982 Lou van den Dries showed that the fact that the field of real numbers is o-minimal gives a large amount of useful information about the definable sets of higher dimension, such as the family of definable subsets of the real plane. Soon after this, Julia Knight, Anand Pillay and Charles Steinhorn noticed that if a structure *A* is o-minimal, then so is any structure elementarily equivalent to *A*, and that Van den Dries' analysis of higher-dimensional definable set applies to all these structures. These results led to much activity on the frontier between model theory and function theory. Several old problems from model theory and function theory were solved. Alex Wilkie showed that the field of real numbers with a symbol for exponentiation is o-minimal and has a model-complete complete theory, and thereby gave a positive answer to Tarski's old problem of whether this structure allows a quantifier elimination (though his method was very far from the syntactic analysis that Tarski had in mind). We now know a wide range of ways of adding interesting features to the field of real numbers in such a way that the resulting structure is still o-minimal (and hence in some sense mathematically tractable). Van den Dries has urged that o-minimal structures provide a good setting for developing the 'tame topology' programme of Alexander Grothendieck.

Model Theory

Model theory began with the study of formal languages and their interpretations, and of the kinds of classification that a particular formal language can make. Mainstream model theory is now a sophisticated branch of mathematics (see the entry on first-order model theory). But in a broader sense, model theory is the study of the interpretation of any language, formal or natural, by means of set-theoretic structures, with Alfred Tarski's truth definition as a paradigm. In this broader sense, model theory meets philosophy at several points, for example in the theory of logical consequence and in the semantics of natural languages.

1. Basic notions of model theory

Sometimes we write or speak a sentence S that expresses nothing either true or false, because some crucial information is missing about what the words mean. If we go on to add this information, so that S comes to express a true or false statement, we are said to *interpret* S, and the added information is called an *interpretation* of S. If the interpretation *I* happens to make S state something true, we say that *I* is a *model* of S, or that *I satisfies* S, in symbols '$I \models$ S'. Another way of saying that *I* is a model of S is to say that S is *true in I*, and so we have the notion of *model-theoretic truth*, which is truth in a particular interpretation. But one should remember that the statement 'S is true in *I*' is just a paraphrase of 'S, when interpreted as in *I*, is true'; so model-theoretic truth is parasitic on plain ordinary truth, and we can always paraphrase it away.

For example I might say

He is killing all of them,

and offer the interpretation that 'he' is Alfonso Arblaster of 35 The Crescent, Beetleford, and that 'them' are the pigeons in his loft. This interpretation explains (a) what objects some expressions refer to, and (b) what classes some quantifiers range over. (In this example there is one quantifier: 'all of them'). Interpretations that consist of items (a) and (b) appear very often in model theory, and they are known as *structures*. Particular kinds of model theory use particular kinds of structure; for example mathematical model theory tends to use so-called *first-order structures*, model theory of modal logics uses *Kripke structures*, and so on.

The structure *I* in the previous paragraph involves one fixed object and one fixed class. Since we described the structure today, the class is the class of pigeons in Alfonso's loft today, not those that will come tomorrow to replace them. If Alfonso Arblaster kills all the pigeons in his loft today, then *I* satisfies the quoted sentence today but won't satisfy it tomorrow, because Alfonso can't kill the same pigeons twice over. Depending on what you want to use model theory for, you may be happy to evaluate sentences today (the default time), or you may want to record how they are satisfied at one time and not at another. In the latter case you can relativise the notion of model and write '$I \models_t S$' to mean that *I* is a model of S at time *t*. The same applies to places, or to anything else that might be picked up by other implicit indexical features in the sentence. For example if you believe in possible worlds, you can index $\models$ by the possible world where the sentence is to be evaluated. Apart from using set theory, model theory is completely agnostic about what kinds of thing exist.

Note that the objects and classes in a structure carry labels that steer them to the right expressions in the sentence. These labels are an essential part of the structure.

If the same class is used to interpret all quantifiers, the class is called the *domain* or *universe* of the structure. But sometimes there are quantifiers ranging over different classes. For example if I say

One of those thingummy diseases is killing all the birds.

you will look for an interpretation that assigns a class of diseases to 'those thingummy diseases' and a class of birds to 'the birds'. Interpretations that give two or more classes for different quantifiers to range over are said to be *many-sorted*, and the classes are sometimes called the *sorts*.

The ideas above can still be useful if we start with a sentence S that does say something either true or false without needing further interpretation. (Model theorists say that such a sentence is *fully interpreted*.) For example we can consider *misinterpretations I* of a fully interpreted sentence S. A misinterpretation of S that makes it true is known as a *nonstandard* or *unintended* model of S. The branch of mathematics called nonstandard analysis is based on nonstandard models of mathematical statements about the real or complex number systems; see Section 4 below.

One also talks of *model-theoretic semantics* of natural languages, which is a way of *describing* the meanings of natural language sentences, not a way of *giving* them meanings. The connection between this semantics and model theory is a little indirect. It lies in Tarski's truth definition of 1933. See the entry on Tarski's truth definitions for more details.

2. Model-theoretic definition

A sentence S divides all its possible interpretations into two classes, those that are models of it and those that are not. In this way it defines a class, namely the class of all its models, written Mod(S). To take a legal example, the sentence

> The first person has transferred the property to the second person, who thereby holds the property for the benefit of the third person.

defines a class of structures which take the form of labelled 4-tuples, as for example (writing the label on the left):

- the first person = Alfonso Arblaster;
- the property = the derelict land behind Alfonso's house;
- the second person = John Doe;
- the third person = Richard Roe.

This is a typical model-theoretic definition, defining a class of structures (in this case, the class known to the lawyers as *trusts*).

We can extend the idea of model-theoretic definition from a single sentence S to a set T of sentences; Mod(T) is the class of all interpretations that are simultaneously models of all the sentences in T. When a set T of sentences is used to define a class in this way, mathematicians say that T is a *theory* or a *set of axioms*, and that T *axiomatises* the class Mod(T).

Take for example the following set of first-order sentences:

$$\forall x \forall y \forall z\ (x + (y + z) = (x + y) + z).$$
$$\forall x\ (x + 0 = x).$$
$$\forall x\ (x + (-x) = 0).$$
$$\forall x \forall y\ (x + y = y + x).$$

Here the labels are the addition symbol '+', the minus symbol '-' and the constant symbol '0'. An interpretation also needs to specify a domain for the quantifiers. With one proviso, the models of this set of sentences are precisely the structures that mathematicians know as *abelian groups*. The proviso is that in an abelian group *A*, the domain should contain the interpretation of the symbol 0, and it should be

closed under the interpretations of the symbols + and -. In mathematical model theory one builds this condition (or the corresponding one for other function and constant symbols) into the definition of a structure.

Each mathematical structure is tied to a particular first-order language. A structure contains interpretations of certain predicate, function and constant symbols; each predicate or function symbol has a fixed arity. The collection K of these symbols is called the *signature* of the structure. Symbols in the signature are often called *nonlogical constants*, and an older name for them is *primitives*. The first-order language of signature K is the first-order language built up using the symbols in K, together with the equality sign =, to build up its atomic formulas. (See the entry on classical logic.) If K is a signature, S is a sentence of the language of signature K and *A* is a structure whose signature is K, then because the symbols match up, we know that *A* makes S either true or false. So one defines the class of abelian groups to be the class of all those structures of signature +, -, 0 which are models of the sentences above. Apart from the fact that it uses a formal first-order language, this is exactly the algebraists' usual definition of the class of abelian groups; model theory formalises a kind of definition that is extremely common in mathematics.

Now the defining axioms for abelian groups have three kinds of symbol (apart from punctuation). First there is the logical symbol = with a fixed meaning. Second there are the nonlogical constants, which get their interpretation by being applied to a particular structure; one should group the quantifier symbols with them, because the structure also determines the domain over which the quantifiers range. And third there are the variables *x*, *y* etc. This three-level pattern of symbols allows us to define classes in a second way. Instead of looking for the interpretations of the nonlogical constants that will make a sentence true, we *fix* the interpretations of the nonlogical constants by choosing a particular structure *A*, and we look for assignments of elements of *A* to variables which will make a given formula true in *A*.

For example let ***Z*** be the additive group of integers. Its elements are the integers (positive, negative and 0), and the symbols +, -, 0 have their usual meanings. Consider the formula

$$v_1 + v_1 = v_2.$$

If we assign the number -3 to v_1 and the number -6 to v_2, the formula works out as true in ***Z***. We express this by saying that the pair (-3,-6) *satisfies* this formula *in **Z***. Likewise (15,30) and (0,0) satisfy it, but (2,-4) and (3,3) don't. Thus the formula *defines* a binary relation on the integers, namely the set of pairs of integers that satisfy it. A relation defined in this way in a structure *A* is called a *first-order definable relation in A*. A useful generalisation is to allow the defining formula to use added names for some specific elements of *A*; these elements are called *parameters* and the relation is then *definable with parameters*.

This second type of definition, defining relations inside a structure rather than classes of structure, also formalises a common mathematical practice. But this time the practice belongs to geometry rather than to algebra. You may recognise the relation in the field of real numbers defined by the formula

$$v_1^2 + v_2^2 = 1.$$

It's the circle of radius 1 around the origin in the real plane. Algebraic geometry is full of definitions of this kind.

During the 1940s it occurred to several people (chiefly Anatolii Mal'tsev in Russia, Alfred Tarski in the USA and Abraham Robinson in Britain) that the metatheorems of classical logic could be used to prove mathematical theorems about classes defined in the two ways we have just described. In 1950 both Robinson and Tarski were invited to address the International Congress of Mathematicians at Cambridge Mass. on this new discipline (which as yet had no name - Tarski proposed the name 'model theory' in 1954). The conclusion of Robinson's address to that Congress is worth quoting:

> [The] concrete examples produced in the present paper will have shown that contemporary symbolic logic can produce useful tools - though by no means omnipotent ones - for the development of actual mathematics, more particularly for the development of algebra and, it would appear, of algebraic geometry. This is the realisation of an ambition which was expressed by Leibnitz in a letter to Huyghens as long ago as 1679.

In fact Mal'tsev had already made quite deep applications of model theory in group theory several years earlier, but under the political conditions of the time his work in Russia was not yet known in the West. By the end of the twentieth century, Robinson's hopes had been amply fulfilled; see the entry on first-order model theory.

There are at least two other kinds of definition in model theory besides these two above. The third is known as *interpretation* (a special case of the interpretations that we began with). Here we start with a structure A, and we build another structure B whose signature need not be related to that of A, by defining the domain X of B and all the labelled relations and functions of B to be the relations definable in A by certain formulas with parameters. A further refinement is to find a definable equivalence relation on X and take the domain of B to be not X itself but the set of equivalence classes of this relation. The structure B built in this way is said to be *interpreted in* the structure A.

A simple example, again from standard mathematics, is the interpretation of the group $\boldsymbol{Z}$ of integers in the structure $\boldsymbol{N}$ consisting of the natural numbers 0, 1, 2 etc. with labels for 0, 1 and +. To construct the domain of $\boldsymbol{Z}$ we first take the set X of all ordered pairs of natural numbers (clearly a definable relation in $\boldsymbol{N}$), and on this set X we define the equivalence relation $\sim$ by

$$(a,b) \sim (c,d) \text{ if and only if } a + d = b + c$$

(again definable). The domain of $\boldsymbol{Z}$ consists of the equivalence classes of this relation. We define addition on $\boldsymbol{Z}$ by

$(a,b) + (c,d) = (e,f)$ if and only if $a + c + f = b + d + e$.

The equivalence class of (a,b) becomes the integer $a - b$.

When a structure *B* is interpreted in a structure *A*, every first-order statement about *B* can be translated back into a first-order statement about *A*, and in this way we can read off the complete theory of *B* from that of *A*. In fact if we carry out this construction not just for a single structure *A* but for a family of models of a theory T, always using the same defining formulas, then the resulting structures will all be models of a theory T′ that can be read off from T and the defining formulas. This gives a precise sense to the statement that the theory T′ is *interpreted in* the theory T. Philosophers of science have sometimes experimented with this notion of interpretation as a way of making precise what it means for one theory to be reducible to another. But realistic examples of reductions between scientific theories seem generally to be much subtler than this simple-minded model-theoretic idea will allow. See the entry on intertheory relations in physics.

The fourth kind of definability is a pair of notions, implicit definability and explicit definability of a particular relation in a theory. See section 3.3 of the entry on first-order model theory.

Unfortunately there used to be a very confused theory about model-theoretic axioms, that also went under the name of implicit definition. By the end of the nineteenth century, mathematical geometry had generally ceased to be a study of space, and it had become the study of classes of structures which satisfy certain 'geometric' axioms. Geometric terms like 'point', 'line' and 'between' survived, but only as the primitive symbols in axioms; they no longer had any meaning associated with them. So the old question, whether Euclid's parallel postulate (as a statement about space) was deducible from Euclid's other assumptions about space, was no longer interesting to geometers. Instead, geometers showed that if one wrote down an up-to-date version of Euclid's other assumptions, in the form of a theory T, then it was possible to find models of T which fail to satisfy the parallel postulate. (See the entry on geometry in the 19th century for the contributions of Lobachevski and Klein to this achievement.) In 1899 David Hilbert published a book in which he constructed such models, using exactly the method of interpretation that we have just described.

Problems arose because of the way that Hilbert and others described what they were doing. The history is complicated, but roughly the following happened. Around the middle of the nineteenth century people noticed, for example, that in an abelian group the minus function is definable in terms of 0 and + (namely: $-a$ is the element b such that $a + b = 0$). Since this description of minus is in fact one of the axioms defining abelian groups, we can say (using a term taken from J. D. Gergonne, who should not be held responsible for the later use made of it) that the axioms for abelian groups *implicitly define* minus. In the jargon of the time, one said not that the axioms define the function minus, but that they define the *concept* minus. Now suppose we switch around and try to define plus in terms of minus and 0. This way round it can't be done, since one can have two abelian groups with the same 0 and minus but different plus functions. Rather than say this, the nineteenth century mathematicians concluded that the axioms only partially define plus in terms of minus and 0. Having swallowed that much, they went on to say that

the axioms together form an implicit definition of the concepts plus, minus and 0 together, and that this implicit definition is only partial but it says about these concepts precisely as much as we need to know.

One wonders how it could happen that for fifty years nobody challenged this nonsense. In fact some people did challenge it, notably the geometer Moritz Pasch who in section 12 of his *Vorlesungen über Neuere Geometrie* (1882) insisted that geometric axioms tell us nothing whatever about the meanings of ‘point’, ‘line’ etc. Instead, he said, the axioms give us *relations* between the concepts. If one thinks of a structure as a kind of ordered *n*-tuple of sets etc., then a class Mod(T) becomes an *n*-ary relation, and Pasch’s account agrees with ours. But he was unable to spell out the details, and there is some evidence that his contemporaries (and some more recent commentators) thought he was saying that the axioms may not determine the meanings of ‘point’ and ‘line’, but they do determine those of relational terms such as ‘between’ and ‘incident with’! Frege’s demolition of the implicit definition doctrine was masterly, but it came too late to save Hilbert from saying, at the beginning of his *Grundlagen der Geometrie*, that his axioms give ‘the exact and mathematically adequate description’ of the relations ‘lie’, ‘between’ and ‘congruent’. Fortunately Hilbert’s mathematics speaks for itself, and one can simply bypass these philosophical faux pas. The model-theoretic account that we now take as a correct description of this line of work seems to have surfaced first in the group around Giuseppe Peano in the 1890s, and it reached the English-speaking world through Bertrand Russell’s *Principles of Mathematics* in 1903.

3. Model-theoretic consequence

Suppose L is a language of signature K, T is a set of sentences of L and φ is a sentence of L. Then the relation

$$\mathrm{Mod}(T) \subseteq \mathrm{Mod}(\varphi)$$

expresses that every structure of signature K which is a model of T is also a model of φ. This is known as the *model-theoretic consequence relation*, and it is written for short as

$$T \models \varphi$$

The double use of $\models$ is a misfortune. But in the particular case where L is first-order, the completeness theorem (see the entry on classical logic) tells us that ‘$T \models \varphi$’ holds if and only if there is a proof of φ from T, a relation commonly written

$$T \vdash \varphi$$

Since $\models$ and $\vdash$ express exactly the same relation in this case, model theorists often avoid the double use of $\models$ by using $\vdash$ for model-theoretic consequence. But since what follows is not confined to first-order languages, safety suggests we stick with $\models$ here.

Before the middle of the nineteenth century, textbooks of logic commonly taught the student how to check the validity of an argument (say in English) by showing that it has one of a number of standard forms, or by paraphrasing it into such a form. The standard forms were syntactic and/or semantic forms of argument in English. The process was hazardous: semantic forms are almost by definition not visible on the surface, and there is no purely syntactic form that guarantees validity of an argument. For this reason most of the old textbooks had a long section on ‘fallacies’ - ways in which an invalid argument may seem to be valid.

In 1847 George Boole changed this arrangement. For example, to validate the argument

> All monarchs are human beings. No human beings are infallible. Therefore no infallible beings are monarchs.

Boole would interpret the symbols P, Q, R as names of classes:

> P is the class of all monarchs.
> Q is the class of all human beings.
> R is the class of all infallible beings.

Then he would point out that the original argument paraphrases into a set-theoretic consequence:

$$(P \subseteq Q), (Q \cap R = 0) \models (R \cap P = 0)$$

(This example is from Stanley Jevons, 1869. Boole’s own account is idiosyncratic, but I believe Jevons’ example represents Boole’s intentions accurately.) Today we would write $\forall x\,(Px \rightarrow Qx)$ rather than $P \subseteq Q$, but this is essentially the standard definition of $P \subseteq Q$, so the difference between us and Boole is slight.

Insofar as they follow Boole, modern textbooks of logic establish that English arguments are valid by reducing them to model-theoretic consequences. Since the class of model-theoretic consequences, at least in first-order logic, has none of the vaguenesses of the old argument forms, textbooks of logic in this style have long since ceased to have a chapter on fallacies.

But there is one warning that survives from the old textbooks: If you formalise your argument in a way that is *not* a model-theoretic consequence, it doesn’t mean the argument is *not valid*. It may only mean that you failed to analyse the concepts in the argument deeply enough before you formalised. The old textbooks used to discuss this in a ragbag section called ‘topics’ (i.e. hints for finding arguments that you might have missed). Here is an example from Peter of Spain’s 13th century *Summulae Logicales*:

> ’There is a father. Therefore there is a child.’ ... Where does the validity of this argument

> come from? From the relation. The maxim is: When one of a correlated pair is posited, then so is the other.

Hilbert and Ackermann, possibly the textbook that did most to establish the modern style, discuss in their section III.3 a very similar example: ‘If there is a son, then there is a father’. They point out that any attempt to justify this by using the symbolism

$$\exists x \, S(x) \rightarrow \exists x \, F(x)$$

is doomed to failure. ‘A proof of this statement is possible only if we analyze conceptually the meanings of the two predicates which occur’, as they go on to illustrate. And of course the analysis finds precisely the relation that Peter of Spain referred to.

On the other hand if your English argument translates into an invalid model-theoretic consequence, a counterexample to the consequence may well give clues about how you can describe a situation that would make the premises of your argument true and the conclusion false. But this is not guaranteed.

One can raise a number of questions about whether the modern textbook procedure does really capture a sensible notion of logical consequence. For example in Boole’s case the set-theoretic consequences that he relies on are all easily provable by formal proofs in first-order logic, not even using any set-theoretic axioms; and by the completeness theorem (see the entry on classical logic) the same is true for first-order logic. But for some other logics it is certainly not true. For instance the model-theoretic consequence relation for some logics of time presupposes some facts about the physical structure of time. Also, as Boole himself pointed out, his translation from an English argument to its set-theoretic form requires us to believe that for every property used in the argument, there is a corresponding class of all the things that have the property. This comes dangerously close to Frege’s inconsistent comprehension axiom!

In 1936 Alfred Tarski proposed a definition of logical consequence for arguments in a fully interpreted formal language. His proposal was that an argument is valid if and only if: under any allowed reinterpretation of its nonlogical symbols, if the premises are true then so is the conclusion. Tarski assumed that the class of allowed reinterpretations could be read off from the semantics of the language, as set out in his truth definition. He left it undetermined what symbols count as nonlogical; in fact he hoped that this freedom would allow one to define different kinds of necessity, perhaps separating ‘logical’ from ‘analytic’. One thing that makes Tarski’s proposal difficult to evaluate is that he completely ignores the question we discussed above, of analysing the concepts to reach all the logical connections between them. The only plausible explanation I can see for this lies in his parenthetical remark about

> the necessity of eliminating any defined signs which may possibly occur in the sentences concerned, i.e. of replacing them by primitive signs.

This suggests to me that he wants his primitive signs to be *by stipulation* unanalysable. But then by

stipulation it will be purely accidental if his notion of logical consequence captures everything one would normally count as a logical consequence.

Historians note a resemblance between Tarski's proposal and one in section 147 of Bernard Bolzano's *Wissenschaftslehre* of 1837. Like Tarski, Bolzano defines the validity of a proposition in terms of the truth of a family of related propositions. Unlike Tarski, Bolzano makes his proposal for propositions in the vernacular, not for sentences of a formal language with a precisely defined semantics.

On all of this section, see also the entry on logical consequence.

4. Expressive strength

A sentence S defines its class Mod(S) of models. Given two languages L and L′, we can compare them by asking whether every class Mod(S), with S a sentence of L, is also a class of the form Mod(S′) where S′ is a sentence of L′. If the answer is Yes, we say that L is *reducible to* L′, or that L′ is *at least as expressive as* L.

For example if L is a first-order language with identity, whose signature consists of 1-ary predicate symbols, and L′ is the language whose sentences consist of the four syllogistic forms (All *A* are *B*, Some *A* are *B*, No *A* are *B*, Some *A* are not *B*) using the same predicate symbols, then L′ is reducible to L, because the syllogistic forms are expressible in first-order logic. (There are some quarrels about which is the right way to express them; see the entry on the traditional square of opposition.) But the first-order language L is certainly not reducible to the language L′ of syllogisms, since in L we can write down a sentence saying that exactly three elements satisfy P(*x*), and there is no way of saying this using just the syllogistic forms. Or moving the other way, if we form a third language L″ by adding to L the quantifier Q*x* with the meaning 'There are uncountably many elements such that ...', then trivially L is reducible to L″, but the downward Loewenheim-Skolem theorem shows at once that L″ is not reducible to *L*.

These notions are useful for analysing the strength of database query languages. We can think of the possible states of a database as structures, and a simple Yes/No query becomes a sentence that elicits the answer Yes if the database is a model of it and No otherwise. If one database query language is not reducible to another, then the second can express some query that can't be expressed in the first.

So we need techniques for comparing the expressive strengths of languages. One of the most powerful techniques available consists of the back-and-forth games of Ehrenfeucht and Fraïssé between the two players Spoiler and Duplicator; see the entry on logic and games for details. Imagine for example that we play the usual first-order back-and-forth game *G* between two structures *A* and *B*. The theory of these games establishes that if some first-order sentence φ is true in exactly one of *A* and *B*, then there is a number *n*, calculable from φ, with the property that Spoiler has a strategy for *G* that will guarantee that he wins in at most *n* steps. So conversely, to show that first-order logic can't distinguish between *A* and *B*, it suffices to show that for any finite *n*, Duplicator has a strategy that will guarantee she doesn't lose *G*

in the first n steps. If we succeed in showing this, it follows that any language which does distinguish between A and B is not reducible to the first-order language of the structures A and B.

These back-and-forth games are immensely flexible. For a start, they make just as much sense on finite structures as they do on infinite; many other techniques of classical model theory assume that the structures are infinite. They can also be adapted smoothly to many non-first-order languages.

In 1969 Per Lindström used back-and-forth games to give some abstract characterisations of first-order logic in terms of its expressive power. One of his theorems says that if L is a language with a signature K, L is closed under all the first-order syntactic operations, and L obeys the downward Loewenheim-Skolem theorem for single sentences, and the compactness theorem, then L is reducible to the first-order language of signature K. These theorems are very attractive; see Chapter XII of Ebbinghaus, Flum and Thomas for a good account. But they have never quite lived up to their promise. It has been hard to find any similar characterisations of other logics. Even for first-order logic it is a little hard to see exactly what the characterisations tell us. But very roughly speaking, they tell us that first-order logic is the unique logic with two properties: (1) we can use it to express arbitrarily complicated things about finite patterns, and (2) it is hopeless for discriminating between one infinite cardinal and another.

These two properties (1) and (2) are just the properties of first-order logic that allowed Abraham Robinson to build his *nonstandard analysis*. The background is that Leibniz, when he invented differential and integral calculus, used infinitesimals, i.e. numbers that are greater than 0 and smaller than all of 1/2, 1/3, 1/4 etc. Unfortunately there are no such real numbers. During the nineteenth century all definitions and proofs in the Leibniz style were rewritten to talk of limits instead of infinitesimals. Now let ***R*** be the structure consisting of the field of real numbers together with any structural features we care to give names to: certainly plus and times, maybe the ordering, the set of integers, the functions sin and log, etc. Let L be the first-order language whose signature is that of ***R***. Because of the expressive strength of L, we can write down any number of theorems of calculus as sentences of L. Because of the expressive weakness of L, there is no way that we can express in L that ***R*** has no infinitesimals. In fact Robinson used the compactness theorem to build a structure $\boldsymbol{R}'$ that is a model of exactly the same sentences of L as ***R***, but which has infinitesimals. As Robinson showed, we can copy Leibniz's arguments using the infinitesimals in $\boldsymbol{R}'$, and so prove that various theorems of calculus are true in $\boldsymbol{R}'$. But these theorems are expressible in L, so they must also be true in ***R***.

Since arguments using infinitesimals are usually easier to visualise than arguments using limits, nonstandard analysis is a helpful tool for mathematical analysts. Jacques Fleuriot in his recent PhD thesis automated the proof theory of nonstandard analysis and used it to mechanise some of the proofs in Newton's *Principia*.

5. Models and modelling

To *model* a phenomenon is to construct a formal theory that describes and explains it. In a closely related sense, you *model* a system or structure that you plan to build, by writing a description of it. These are

very different senses of ‘model’ from that in model theory: the ‘model’ of the phenomenon or the system is not a structure but a theory, often in a formal language. The *Universal Modeling Language*, UML for short, is a formal language designed for just this purpose. It’s reported that the Australian Navy once hired a model theorist for a job ‘modelling hydrodynamic phenomena’. (Please don’t enlighten them!)

In cognitive science the difference between models and modelling has become blurred. A central question of cognitive science is how we represent facts or possibilities in our minds. If one formalises these mental representations, they become something like ‘models of phenomena’. But it is a serious hypothesis that in fact our mental representations have a good deal in common with simple set-theoretic structures, so that they are ‘models’ in the model-theoretic sense too. In 1983 two influential works of cognitive science were published, both under the title *Mental Models*. The first, edited by Dedre Gentner and Albert Stevens, was about people’s ‘conceptualizations’ of the elementary facts of physics; it belongs squarely in the world of ‘modelling of phenomena’. The second, by Philip Johnson-Laird, is largely about reasoning, and makes considerable use of ‘model-theoretic semantics’ in our sense. Researchers in the Johnson-Laird tradition tend to refer to their approach as ‘model theory’, and to see it as allied in some sense to what we have called model theory. (The book by Alan Garnham in the references is a recent work in this line.)

Pictures and diagrams seem at first to hover in the middle ground between theories and models. In practice model theorists often draw themselves pictures of structures, and use the pictures to think about the structures. On the other hand pictures don’t generally carry the labelling that is an essential feature of model-theoretic structures. There is a fast growing body of work on reasoning with diagrams, and the overwhelming tendency of this work is to see pictures and diagrams as a form of language rather than as a form of structure. For example Eric Hammer and Norman Danner (in the book edited by Allwein and Barwise, see the Bibliography) describe a ‘model theory of Venn diagrams’; the Venn diagrams themselves are the syntax, and the model theory is a set-theoretical explanation of their meaning.

The model theorist Yuri Gurevich introduced *abstract state machines* (ASMs) as a way of using model-theoretic ideas for specification in computer science. According to the Abstract State Machine website (see Other Internet Resources below),

> One uses a specification methodology to describe a system by means of a particular syntax and associated semantics. If the semantics of the specification methodology is unclear, descriptions using the methodology may be no clearer than the original systems being described. ASMs use classical mathematical structures to describe states of a computation; structures are well-understood, precise models.

The book of Staerk et al. in the Bibliography is an example of ASMs at work.

Today you can make your name and fortune by finding a good representation system. There is no reason to expect that every such system will fit neatly into the syntax/semantics framework of model theory, but it will be surprising if model-theoretic ideas don’t continue to make a major contribution in this area.

Tarski's Truth Definitions

In 1933 the Polish logician Alfred Tarski published a paper in which he discussed the criteria that a definition of 'true sentence' should meet, and gave examples of several such definitions for particular formal languages. In 1956 he and his colleague Robert Vaught published a revision of one of the 1933 truth definitions, to serve as a truth definition for model-theoretic languages. In this entry, we simply review the definitions and make no attempt to explore the implications of Tarski's work for semantics (natural language or programming languages) or for the philosophical study of truth.

1. The 1933 programme and the semantic conception

In the 1920s Alfred Tarski embarked on a project to give rigorous definitions for notions useful in scientific methodology. In 1933 he published (in Polish) his analysis of the notion of a true sentence. This long paper undertook two tasks: first to say what should count as a satisfactory definition of 'true sentence' for a given formal language, and second to show that there do exist satisfactory definitions of 'true sentence' for a range of formal languages. We begin with the first task; Section 2 will consider the second.

We say that a language is *fully interpreted* if all its sentences have meanings that make them either true or false. All the languages that Tarski considered in the 1933 paper were fully interpreted, with one exception described in Section 2.2 below. This was the main difference between the 1933 definition and the later model-theoretic definition of 1956, which we shall examine in Section 3.

Tarski described several conditions that a satisfactory definition of truth should meet.

1.1 Object language and metalanguage

If the language under discussion (the *object language*) is L, then the definition should be given in another language known as the *metalanguage*, call it M. The metalanguage should contain a copy of the object language (so that anything one can say in L can be said in M too), and M should also be able to talk about the sentences of L and their syntax. Finally Tarski allowed M to contain notions from set theory, and a 1-ary predicate symbol *True* with the intended reading 'is a true sentence of L'. The main purpose of the metalanguage was to formalise what was being said about the object language, and so Tarski also required that the metalanguage should carry with it a set of axioms expressing everything that one needs to assume for purposes of defining and justifying the truth definition. The truth definition itself was to be a definition of *True* in terms of the other expressions of the metalanguage. So the definition was to be in terms of syntax, set theory and the notions expressible in L, but not semantic notions like 'denote' or 'mean' (unless the object language happened to contain these notions).

Tarski assumed, in the manner of his time, that the object language L and the metalanguage M would be languages of some kind of higher order logic. Today it is more usual to take some kind of informal set theory as one's metalanguage; this would affect some details of Tarski's paper but not its main thrust. Also today it is usual to define syntax in set-theoretic terms, so that for example a string of letters becomes a sequence. In fact one must use a set-theoretic syntax if one wants to work with an object language that has uncountably many symbols, as model theorists have done freely for over half a century now.

1.2 Formal correctness

The definition of *True* should be 'formally correct'. This means that it should be a sentence of the form

For all x, *True*(x) if and only if $\varphi(x)$,

where *True* never occurs in φ; or failing this, that the definition should be provably equivalent to a sentence of this form. The equivalence must be provable using axioms of the metalanguage that don't contain *True*. Definitions of the kind displayed above are usually called *explicit*, though Tarski in 1933 called them *normal*.

1.3 Material adequacy

The definition should be 'materially adequate'. This means that the objects satisfying φ should be exactly the objects that we would intuitively count as being true sentences of L, and that this fact should be provable from the axioms of the metalanguage. At first sight this is a paradoxical requirement: if we can prove what Tarski asks for, just from the axioms of the metalanguage, then we must already have a materially adequate formalisation of 'true sentence of L' within the metalanguage, suggesting an infinite

regress. In fact Tarski escapes the paradox by using (in general) infinitely many sentences of M to express truth, namely all the sentences of the form

$\varphi(s)$ if and only if ψ

whenever *s* is the name of a sentence S of L and ψ is the copy of S in the metalanguage. So the technical problem is to find a single formula φ that allows us to deduce all these sentences from the axioms of M; this formula φ will serve to give the explicit definition of *True*.

Tarski's own name for this criterion of material adequacy was *Convention T*. More generally his name for his approach to defining truth, using this criterion, was *the semantic conception of truth*.

As Tarski himself emphasised, Convention T rapidly leads to the liar paradox if the language L has enough resources to talk about its own semantics. (See the entry on the revision theory of truth.) Tarski's own conclusion was that a truth definition for a language L has to be given in a metalanguage which is essentially stronger than L.

There is a consequence for the foundations of mathematics. First-order Zermelo-Fraenkel set theory is widely regarded as the standard of mathematical correctness, in the sense that a proof is correct if and only if it can be formalised as a formal proof in set theory. We would like to be able to give a truth definition for set theory; but by Tarski's result this truth definition can't be given in set theory itself. The usual solution is to give the truth definition informally in English. But there are a number of ways of giving limited formal truth definitions for set theory. For example Azriel Levy showed that for every natural number *n* there is a Σ_n formula that is satisfied by all and only the set-theoretic names of true Σ_n sentences of set theory. The definition of Σ_n is too technical to give here, but three points are worth making. First, every sentence of set theory is provably equivalent to a Σ_n sentence for any large enough *n*. Second, the class of Σ_n formulas is closed under adding existential quantifiers at the beginning, but not under adding universal quantifiers. Third, the class is not closed under negation; this is how Levy escapes Tarski's paradox. (See the entry on set theory.) Essentially the same devices allow Jaakko Hintikka to give an internal truth definition for his Independence-Friendly Logic; this logic shares the second and third properties of Levy's classes of formulas.

2. Some kinds of truth definition on the 1933 pattern

In his 1933 paper Tarski went on to show that many fully interpreted formal languages do have a truth definition that satisfies his conditions. He gave four examples in that paper. One was a trivial definition for a finite language; it simply listed the finitely many true sentences. One was a definition by quantifier elimination; see Section 2.2 below. The remaining two, for different classes of language, were examples

of what people today think of as the standard Tarski truth definition; they are forerunners of the 1956 model-theoretic definition.

2.1 The standard truth definitions

The two standard truth definitions are at first glance not definitions of truth at all, but definitions of a more complicated relation involving assignments *a* of objects to variables:

> *a* satisfies the formula F.

In fact satisfaction reduces to truth in this sense: *a* satisfies F if and only if taking each free variable in F as a name of the object assigned to it by *a* makes F into a true sentence. So it follows that our intuitions about when a sentence is true can guide our intuitions about when an assignment satisfies a formula. But none of this can enter into the formal definition of truth, because ‘taking a variable as a name of an object’ is a semantic notion, and Tarski’s truth definition has to be built only on notions from syntax and set theory (together with those in the object language); recall Section 1.1. In fact Tarski’s reduction goes in the other direction: if F has no free variables, then to say that F is true is to say that every assignment satisfies it.

The reason why Tarski defines satisfaction directly, and then deduces a definition of truth, is that satisfaction obeys *recursive conditions* in the following sense: if F is a compound formula, then to know which assignments satisfy F, it’s enough to know which assignments satisfy the immediate constituents of F. Here are two typical examples:

- The assignment *a* satisfies the formula ‘F *and* G’ if and only if *a* satisfies F and *a* satisfies G.
- The assignment *a* satisfies the formula ‘*For all x*, G’ if and only if for every individual *i*, if *b* is the assignment that assigns *i* to the variable *x* and is otherwise exactly like *a*, then *b* satisfies G.

We have to use a different approach for atomic formulas. But for these, at least assuming for simplicity that L has no function symbols, we can use the metalanguage copies #(R) of the predicate symbols R of the object language. Thus:

- The assignment *a* satisfies the formula R(*x*,*y*) if and only if #(R)(*a*(*x*),*a*(*y*)).

(Warning: the expression # is in the metametalanguage, not in the metalanguage M. We may or may not be able to find a formula of M that expresses # for predicate symbols; it depends on exactly what the language L is.)

One sometimes says that Tarski’s definition of satisfaction is *compositional*, meaning that the class of assignments which satisfy a compound formula F is determined solely by (1) the syntactic rule used to construct F from its immediate constituents and (2) the classes of assignments that satisfy these immediate constituents. (This is sometimes phrased loosely as: satisfaction is defined recursively. But

this formulation misses the central point, that (1) and (2) don't contain any syntactic information about the immediate constituents.) Compositionality explains why Tarski switched from truth to satisfaction. You can't define whether '*For all x*, G' is true in terms of whether G is true, because in general G has a free variable *x* and so it isn't either true or false.

The name 'compositionality' is from a paper of Katz and Fodor in 1963 on natural language semantics. In talking about compositionality, we have moved to thinking of Tarski's definition as a semantics, i.e. a way of assigning 'meanings' to formulas. (Here we take the meaning of a sentence to be its truth value.) Compositionality means essentially that the meanings assigned to formulas give *at least* enough information to determine the truth values of sentences containing them. One can ask conversely whether Tarski's semantics provides *only as much information as we need* about each formula, in order to reach the truth values of sentences. If the answer is yes, we say that the semantics is *fully abstract* (for truth). One can show fairly easily, for any of the standard languages of logic, that Tarski's definition of satisfaction is in fact fully abstract.

As it stands, Tarski's definition of satisfaction is not an explicit definition, because satisfaction for one formula is defined in terms of satisfaction for other formulas. So to show that it is formally correct, we need a way of converting it to an explicit definition. One way to do this is as follows, using either higher order logic or set theory. Suppose we write S for a binary relation between assignments and formulas. We say that S is a *satisfaction relation* if for every formula G, S meets the conditions put for satisfaction of G by Tarski's definition. For example, if G is 'G_1 *and* G_2', S should satisfy the following condition for every assignment *a*:

> $S(a,G)$ if and only if $S(a,G_1)$ and $S(a,G_2)$.

We can define 'satisfaction relation' formally, using the recursive clauses and the conditions for atomic formulas in Tarski's recursive definition. Now we prove, by induction on the complexity of formulas, that there is exactly one satisfaction relation S. (There are some technical subtleties, but it can be done.) Finally we define

> *a* satisfies F if and only if: there is a satisfaction relation S such that $S(a,F)$.

It is then a technical exercise to show that this definition of satisfaction is materially adequate. Actually one must first write out the counterpart of Convention T for satisfaction of formulas, but I leave this to the reader.

2.2 The truth definition by quantifier elimination

The remaining truth definition in Tarski's 1933 paper -- the third as they appear in the paper - is really a bundle of related truth definitions, all for the same object language L but in different interpretations. The quantifiers of L are assumed to range over a particular class, call it *A*; in fact they are second order

quantifiers, so that really they range over the collection of subclasses of *A*. The class *A* is not named explicitly in the object language, and thus one can give separate truth definitions for different values of *A*, as Tarski proceeds to do. So for this section of the paper, Tarski allows one and the same sentence to be given different interpretations; this is the exception to the general claim that his object language sentences are fully interpreted. But Tarski stays on the straight and narrow: he talks about 'truth' only in the special case where *A* is the class of all individuals. For other values of *A*, he speaks not of 'truth' but of 'correctness in the domain *A*'.

These truth or correctness definitions don't fall out of a definition of satisfaction. In fact they go by a much less direct route, which Tarski describes as a 'purely accidental' possibility that relies on the 'specific peculiarities' of the particular object language. It may be helpful to give a few more of the technical details than Tarski does, in a more familiar notation than Tarski's, in order to show what is involved. Tarski refers his readers to a paper of Thoralf Skolem in 1919 for the technicalities.

One can think of the language L as the first-order language with predicate symbols ⊆ and =. The language is interpreted as talking about the subclasses of the class *A*. In this language we can define:

- '*x* is the empty set' (viz. *x* ⊆ every class).
- '*x* is an atom' (viz. *x* is not empty, but every subclass of *x* not equal to *x* is empty).
- '*x* has exactly *k* members' (where *k* is a finite number; viz. there are exactly *k* distinct atoms ⊆ *x*).
- 'There are exactly *k* elements in *A*' (viz. there is a class with exactly *k* members, but there is no class with exactly *k*+1 members).

Now we aim to prove:

> *Lemma*. Every formula F of L is equivalent to (i.e. is satisfied by exactly the same assignments as) some boolean combination of sentences of the form 'There are exactly *k* elements in *A*' and formulas of the form 'There are exactly *k* elements that are in v_1, not in v_2, not in v_3 and in v_4' (or any other combination of this type, using only variables free in F).

The proof is by induction on the complexity of formulas. For atomic formulas it is easy. For boolean combinations of formulas it is easy, since a boolean combination of boolean combinations is again a boolean combination. For formulas beginning with ∀, we take the negation. This leaves just one case that involves any work, namely the case of a formula beginning with an existential quantifier. By induction hypothesis we can replace the part after the quantifier by a boolean combination of formulas of the kinds stated. So a typical case might be:

> ∃*z* (there are exactly two elements that are in *z* and *x* and not in *y*).

This holds if and only if there are at least two elements that are in *x* and not in *y*. We can write this in turn

as: The number of elements in *x* and not in *y* is not 0 and is not 1; which is a boolean combination of allowed formulas. The general proof is very similar but more complicated.

When the lemma has been proved, we look at what it says about a sentence. Since the sentence has no free variables, the lemma tells us that it is equivalent to a boolean combination of statements saying that *A* has a given finite number of elements. So if we know how many elements *A* has, we can immediately calculate whether the sentence is 'correct in the domain *A*'.

One more step and we are home. As we prove the lemma, we should gather up any facts that can be stated in L, are true in every domain, and are needed for proving the lemma. For example we shall almost certainly need the sentence saying that $\subseteq$ is transitive. Write T for the set of all these sentences. (In Tarski's presentation T vanishes, since he is using higher order logic and the required statements about classes become theorems of logic.) Thus we reach, for example:

> *Theorem*. If the domain *A* is infinite, then a sentence S of the language L is correct in *A* if and only if S is deducible from T and the sentences saying that the number of elements of *A* is not any finite number.

The class of *all* individuals is infinite (Tarski asserts), so the theorem applies when *A* is this class. And in this case Tarski has no inhibitions about saying not just 'correct in *A*' but 'true'; so we have our truth definition.

The method we have described revolves almost entirely around removing existential quantifiers from the beginnings of formulas; so it is known as *the method of quantifier elimination*. It is not as far as you might think from the two standard definitions. In all cases Tarski assigns to each formula, by induction on the complexity of formulas, a description of the class of assignments that satisfy the formula. In the two previous truth definitions this class is described directly; in the quantifier elimination case it is described in terms of a boolean combination of formulas of a simple kind.

At around the same time as he was writing the 1933 paper, Tarski gave a truth definition by quantifier elimination for the first-order language of the field of real numbers. He published it separately, and at first only as an interesting way of characterising the relations definable by formulas. Later he gave a fuller account, emphasising that his method provided not just a truth definition but an algorithm for determining which sentences about the real numbers are true and which are false.

3. The 1956 definition and its offspring

In 1933 Tarski assumed that the formal languages that he was dealing with had two kinds of symbol (apart from punctuation), namely constants and variables. The constants included logical constants, but also any other terms of fixed meaning. The variables had no independent meaning and were simply part of the apparatus of quantification.

Model theory by contrast works with three levels of symbol. There are the logical constants (=, ¬, ∧ for example), the variables (as before), and between these a middle group of symbols which have no fixed meaning but get a meaning through being applied to a particular structure. The symbols of this middle group include the nonlogical constants of the language, such as relation symbols, function symbols and constant individual symbols. They also include the quantifier symbols ∀ and ∃, since we need to refer to the structure to see what set they range over. This type of three-level language corresponds to mathematical usage; for example we write the addition operation of an abelian group as +, and this symbol stands for different functions in different groups.

So one has to work a little to apply the 1933 definition to model-theoretic languages. There are basically two approaches: (1) Take one structure *A* at a time, and regard the nonlogical constants as constants, interpreted in *A*. (2) Regard the nonlogical constants as variables, and use the 1933 definition to describe when a sentence is satisfied by an assignment of the ingredients of a structure *A* to these variables. There are problems with both these approaches, as Tarski himself describes in several places. The chief problem with (1) is that in model theory we very frequently want to use the same language in connection with two or more different structures - for example when we are defining elementary embeddings between structures (see the entry on first-order model theory). The problem with (2) is more abstract: it is disruptive and bad practice to talk of formulas with free variables being 'true'. (We saw in Section 2.2 how Tarski avoided talking about truth in connection with sentences that have varying interpretations.) What Tarski did in practice, from the appearance of his textbook in 1936 to the late 1940s, was to use a version of (2) and simply avoid talking about model-theoretic sentences being true in structures; instead he gave an indirect definition of what it is for a structure to be a 'model of' a sentence, and apologised that strictly this was an abuse of language. (Chapter VI of Tarski 1994 still contains relics of this old approach.)

By the late 1940s it had become clear that a direct model-theoretic truth definition was needed. Tarski and colleagues experimented with several ways of casting it. The version we use today is based on that published by Tarski and Robert Vaught in 1956. See the entry on classical logic for an exposition.

The right way to think of the model-theoretic definition is that we have sentences whose truth value varies according to the situation where they are used. So the nonlogical constants are not variables; they are definite descriptions whose reference depends on the context. Likewise the quantifiers have this indexical feature, that the domain over which they range depends on the context of use. In this spirit one can add other kinds of indexing. For example a Kripke structure is an indexed family of structures, with a relation on the index set; these structures and their close relatives are fundamental for the semantics of modal, temporal and intuitionist logic.

Already in the 1950s model theorists were interested in formal languages that include kinds of expression different from anything in Tarski's 1933 paper. Extending the truth definition to infinitary logics was no problem at all. Nor was there any serious problem about most of the generalised quantifiers proposed at the time. For example there is a quantifier Q*xy* with the intended meaning:

> $QxyF(x,y)$ if and only if there is an infinite set X of elements such that for all a and b in X, $F(a,b)$.

This definition itself shows at once how the required clause in the truth definition should go.

In 1961 Leon Henkin pointed out two sorts of model-theoretic language that didn't immediately have a truth definition of Tarski's kind. The first had infinite strings of quantifiers:

$$\forall v_1\ \exists v_2\ \forall v_3\ \exists v_4 \ldots R(v_1,v_2,v_3, v_4,\ldots).$$

The second had quantifiers that are not linearly ordered. For ease of writing I use Hintikka's later notation for these:

$$\forall v_1\ \exists v_2\ \forall v_3\ (\exists v_4/\forall v_1)\ R(v_1,v_2,v_3, v_4).$$

Here the slash after $\exists v_4$ means that this quantifier is outside the scope of the earlier quantifier $\forall v_1$ (and also outside that of the earlier existential quantifier).

Henkin pointed out that in both cases one could give a natural semantics in terms of Skolem functions. For example the second sentence can be paraphrased as

$$\exists f \exists g\ \forall v_1\ \forall v_3\ R(v_1,f(v_1),v_3,g(v_3)),$$

which has a straightforward Tarski truth condition in second order logic. Hintikka then observed that one can read the Skolem functions as winning strategies in a game, as in (the entry on) logic and games. In this way one can build up a compositional semantics, by assigning to each formula a game. A sentence is true if and only if the player Myself (in Hintikka's nomenclature) has a winning strategy for the game assigned to the sentence. This game semantics agrees with Tarski's on conventional first-order sentences. But it is far from fully abstract; probably one should think of it as an operational semantics, describing how a sentence is verified rather than whether it is true.

The problem of giving a Tarski-style semantics for Henkin's two languages turned out to be different in the two cases. With the first, the problem is that the syntax of the language is not well-founded: there is an infinite descending sequence of subformulas as one strips off the quantifiers one by one. Hence there is no hope of giving a definition of satisfaction by recursion on the complexity of formulas. The remedy is to note that the *explicit* form of Tarski's truth definition in Section 2.1 above didn't require a recursive definition; it needed only that the conditions on the satisfaction relation S pin it down uniquely. For Henkin's first style of language this is still true, though the reason is no longer the well-foundedness of the syntax.

For Henkin's second style of language, at least in Hintikka's notation, the syntax is well-founded, but the displacement of the quantifier scopes means that the usual quantifier clauses in the definition of satisfaction no longer work. To get a compositional and fully abstract semantics, one has to ask not what assignments of variables satisfy a formula, but what *sets* of assignments satisfy the formula 'uniformly', where 'uniformly' means 'independent of assignments to certain variables, as shown by the slashes on quantifiers inside the formula'. Henkin's second example is of more than theoretical interest, because clashes between the semantic and the syntactic scope of quantifiers occur very often in natural languages.

Logic and games

Games between two players, of the kind where one player wins and one loses, became a familiar tool in many branches of logic during the second half of the twentieth century. Important examples are semantic games used to define truth, back-and-forth games used to compare structures, and dialogue games to express (and perhaps explain) formal proofs.

1. Games in the History of Logic

The links between logic and games go back a long way. If one thinks of a debate as a kind of game, then Aristotle already made the connection; his writings about syllogism are closely intertwined with his study of the aims and rules of debating. Aristotle's viewpoint survived into the common medieval name for logic: *dialectics*. Ramist logic, which drove out the old School logic in the mid sixteenth century, aimed to provide a set of practical tools for the orator and the debater. That view of logic had faded away by the eighteenth century. But in the mid twentieth century Charles Hamblin revived the link between dialogue and the rules of sound reasoning, soon after Paul Lorenzen had connected dialogue to constructive foundations of logic.

A different strand, not quite so old, is the use of games for teaching logic. This is probably the right way to think of the medieval game of ‘obligationes’, where a debater tries to drive his opponent into an unnecessary contradiction. We have at least two textbooks of logic from the early sixteenth century that

present it as a game for an individual student, and Lewis Carroll's *The Game of Logic* (1887) is a more recent example in the same genre.

Mathematical game theory was founded in the early twentieth century. Although no mathematical links with logic emerged until the 1950s, it is striking how many of the early pioneers of game theory are also known for their contributions to logic: John Kemeny, J. C. C. McKinsey, John von Neumann, Willard Quine, Julia Robinson, Ernst Zermelo and others. In 1953 David Gale and Frank Stewart made fruitful connections between set theory and games. Shortly afterwards Leon Henkin suggested a way of using games to give semantics for infinitary languages.

The first half of the twentieth century was an era of increasing rigour and professionalism in logic, and to most logicians of that period the use of games in logic would probably have seemed frivolous. The intuitionist L. E. J. Brouwer expressed this attitude when he accused his opponents of causing mathematics ‘to degenerate into a game’ (as David Hilbert quoted him in 1927). Wittgenstein's language games provoked little response from the logicians. But in the second half of the century the centre of gravity of logical research moved from foundations to techniques, and from about 1960 games were used more and more often in logical papers.

2. Logical Games

From the point of view of game theory, the games that appear in logic are not at all typical. They normally involve just two players, they often have infinite length, the only outcomes are winning and losing, and no probabilities are attached to actions or outcomes. The barest essentials of a logical game are as follows.

There are two players. In general we can call them $\forall$ and $\exists$. The pronunciations ‘Abelard’ and ‘Eloise’ go back to the mid 1980s and usefully fix the players as male and female (though feminist logicians have asked about the propriety of this type-casting). Other names are in common use for the players in particular types of logical game.

The players play by choosing elements of a set Ω, called the *domain* of the game. As they choose, they build up a sequence

$$a_0, a_1, a_2, \ldots$$

of elements of Ω. Infinite sequences of elements of Ω are called *plays*. Finite sequences of elements of Ω are called *positions*; they record where a play might have got to by a certain time. A function τ (the *turn function* or *player function*) takes each position **a** to either $\exists$ or $\forall$; if τ(**a**) = $\exists$, this means that when the game has reached **a**, player $\exists$ makes the next choice (and likewise with $\forall$). The game rules define two sets $W\forall$ and $W\exists$ consisting of positions and plays, with the following properties: if a position **a** is in $W\forall$ then so is any play or longer position that starts with **a** (and likewise with $W\exists$); and no play is in both W

∀ and W∃. We say that player ∀ *wins* a play **b**, and that **b** is a *win* for ∀, if **b** is in W∀; if some position **a** that is an initial segment of **b** is in W∀, then we say that player ∀ *wins already at* **a**. (And likewise with ∃ and W∃.) So to summarise, a logical game is a 4-tuple (Ω, τ, W∀, W∃) with the properties just described.

We say that a logical game is *total* if every play is in either W∀ or W∃, so that there are no draws. Unless one makes an explicit exception, logical games are always assumed to be total. (Don't confuse being total with the much stronger property of being determined -- see below.)

It is only for mathematical convenience that the definition above expects the game to continue to infinity even when a player has won at some finite position; there is no interest in anything that happens after a player has won. Many logical games have the property that in every play, one of the players has already won at some finite position; games of this sort are said to be *well-founded*. An even stronger condition is that there is some finite number *n* such that in every play, one of the players has already won by the *n*-th position; in this case we say that the game has *finite length*.

A *strategy* for a player is a set of rules that describe exactly how that player should choose, depending on how the other player has chosen at earlier moves. Mathematically, a strategy for ∀ consists of a function which takes each position **a** with τ(**a**) = ∀ to an element *b* of Ω; we think of it as an instruction to ∀ to choose *b* when the game has reached the position **a**. (Likewise with a strategy for ∃.) A strategy for a player is said to be *winning* if that player wins every play in which he or she uses the strategy, regardless of what the other player does. At most one of the players has a winning strategy (since otherwise the players could play their winning strategies against each other, and both would win, contradicting that W∀ and W∃ have no plays in common). Occasionally one meets situations in which it seems that two players have winning strategies (for example in the forcing games below), but closer inspection shows that the two players are in fact playing different games.

A game is said to be *determined* if one or other of the players has a winning strategy. There are many examples of games that are not determined, as Gale and Stewart showed in 1953 using the axiom of choice. This discovery led to important applications of the notion of determinacy in the foundations of set theory. Gale and Stewart also proved an important theorem that bears their name: Every well-founded game is determined. It follows that every game of finite length is determined -- a fact already known to Zermelo in 1913. (A more precise statement of the Gale-Stewart theorem is this. A game G is said to be *closed* if ∃ wins every play of G in which she hasn't lost at any finite position. The theorem states that every closed game is determined.)

In most applications of logical games, the central notion is that of a winning strategy for the player ∃. Often these strategies (or their existence) turn out to be equivalent to something of logical importance that could have been defined without using games -- for example a proof. But games are felt to give a better definition because they quite literally supply some motivation: ∃ is trying to win. This raises a question that is not of much interest mathematically, but it should concern philosophers who use logical games. If we want ∃'s motivation in a game G to have any explanatory value, then we need to understand

what is achieved if ∃ does win. In particular we should be able to tell a realistic story of a situation in which some agent called ∃ is trying to do something intelligible, and doing it is the same thing as winning in the game. As Richard Dawkins said, raising the corresponding question for the evolutionary games of Maynard Smith,

> The whole purpose of our search ... is to discover a suitable actor to play the leading role in our metaphors of purpose. We ... want to say, ‘It is for the good of ... ‘. Our quest in this chapter is for the right way to complete that sentence. (*The Extended Phenotype*, Oxford University Press, Oxford 1982, page 91.)

For future reference let us call this the *Dawkins question*. In many kinds of logical game it turns out to be distinctly harder to answer than the pioneers of these games realised.

Just as in classical game theory, the definition of logical games above serves as a clothes horse that we can hang other concepts onto. For example it is common to have some laws that describe what elements of Ω are available for a player to choose at a particular move. Strictly this refinement is unnecessary, because the winning strategies are not affected if we decree instead that a player who breaks the law loses immediately; but for many games this way of viewing them seems unnatural. (For example in Jaakko Hintikka's semantic games, some steps expect a player to choose an element of the structure, whereas other steps require a player to choose a formula. We may as well make it a law that the players must choose elements of these kinds.) A subtler extension is to restrict the information available to the players, so that the games are of imperfect information. Hintikka has explored this possibility in his Game-Theoretic Semantics.

3. Semantic Games

In the early 1930s Alfred Tarski proposed a definition of truth. His definition consisted of a necessary and sufficient condition for a sentence in the language of a typical formal theory to be true; his necessary and sufficient condition used only notions from syntax and set theory, together with the primitive notions of the formal theory in question. In fact Tarski defined the more general relation ‘formula $\varphi(x_1,...,x_n)$ is true of the elements $a_1,..., a_n$’; truth of a sentence is the special case where $n = 0$. For example the question whether

> ‘For all *x* there is *y* such that R(*x*,*y*)’ is true

reduces to the question whether the following holds:

> For every object *a* the sentence ‘There is *y* such that R(*a*,*y*)’ is true.

This in turn reduces to:

For every object *a* there is an object *b* such that the sentence ‘R(*a*,*b*)’ is true.

In this example, that's as far as Tarski's truth definition will take us.

In the late 1950s Leon Henkin noticed that we can intuitively understand some sentences which can't be handled by Tarski's definition. Take for example the infinitely long sentence

For all x_0 there is y_0 such that for all x_1 there is y_1 such that ... $R(x_0,y_0,x_1, y_1,...)$.

Tarski's approach fails because the string of quantifiers at the beginning is infinite, and we would never reach an end of stripping them off. Instead, Henkin suggested, we should consider the game where a person ∀ chooses an object a_0 for x_0, then a second peson ∃ chooses an object b_0 for y_0, then ∀ chooses a_1 for x_1, ∃ chooses b_1 for y_1 and so on. A play of this game is a win for ∃ if and only if the infinite atomic sentence

$R(a_0,b_0,a_1, b_1,...)$

is true. The original sentence is true if and only if player ∃ has a winning strategy for this game. Strictly Henkin used the game only as a metaphor, and the truth condition that he proposed was that the skolemised version of the sentence is true, i.e. that there are functions f_0, f_1, ... such that for every choice of a_0, a_1, a_2 etc. we have

$R(a_0,f_0 (a_0),a_1,f_1 (a_0,a_1),a_2, f_2(a_0,a_1,a_2), ...)$.

But this condition translates immediately into the language of games; the Skolem functions f_0 etc. are a winning strategy for ∃, telling her how to choose in the light of earlier choices by ∀. (It came to light sometime later that C. S. Peirce had already suggested explaining the difference between ‘every’ and ‘some’ in terms of who chooses the object; for example in his second Cambridge Conference lecture of 1898.)

Soon after Henkin's work, Jaakko Hintikka added that the same idea applies with conjunctions and disjunctions. We can regard a conjunction ‘$\varphi \wedge \psi$’ as a universally quantified statement expressing ‘Every one of the sentences φ, ψ holds’, so it should be for the player ∀ to choose one of the sentences. As Hintikka put it, to play the game $G(\varphi \wedge \psi)$, ∀ chooses whether the game should proceed as $G(\varphi)$ or as $G(\psi)$. Likewise disjunctions become existentially quantified statements about sets of sentences, and they mark moves where the player ∃ chooses how the game should proceed. To bring quantifiers into the same style, he proposed that the game $G(\forall x\, \varphi(x))$ proceeds thus: player ∀ chooses an object and provides a name *a* for it, and the game proceeds as $G(\varphi(a))$. (And likewise with existential quantifiers, except that ∃ chooses.) Hintikka also made an ingenious suggestion for introducing negation. Each game G has a *dual game* which is the same as G except that the players ∀ and ∃ are transposed in both the rules

for playing and the rules for winning. The game G(¬φ) is the dual of G(φ).

One can prove that for any first-order sentence φ, interpreted in a fixed structure *A*, player ∃ has a winning strategy for Hintikka's game G(φ) if and only if φ is true in *A* in the sense of Tarski. Two features of this proof are interesting. First, if φ is any first-order sentence then the game G(φ) has finite length, and so the Gale-Stewart theorem tells us that it is determined. We infer that ∃ has a winning strategy in exactly one of G(φ) and its dual; so she has a winning strategy in G(¬φ) if and only if she doesn't have one in G(φ). This takes care of negation. And second, if ∃ has a winning strategy for each game G(φ(*a*)), then after choosing one such strategy f_a for each *a*, she can string them together into a single winning strategy for G(∀*x* φ(*x*)) (namely, ‘Wait and see what element *a* ∀ chooses, then play f_a’). This takes care of the clause for universal quantifiers; but the argument uses the axiom of choice, and in fact it is not hard to see that the equivalence of Hintikka's and Tarski's definitions of truth is equivalent to the axiom of choice (given the other axioms of Zermelo-Fraenkel set theory).

It's puzzling that we have here two theories of when a sentence is true, and the theories are not equivalent if the axiom of choice fails. In fact the reason is not very deep. The axiom of choice is needed not because the Hintikka definition uses games, but because it assumes that strategies are deterministic, i.e. that they are single-valued functions giving the user no choice of options. A more natural way of translating the Tarski definition into game terms is to use nondeterministic strategies. (However, Hintikka insists that the correct explication of ‘true’ is the one using deterministic strategies, and so it is Tarski's definition that works only accidentally.)

Computer implementations of these games of Hintikka proved to be a very effective way of teaching the meanings of first-order sentences. One such package was designed by Jon Barwise and John Etchemendy at Stanford and marketed as ‘Tarski's World’. Independently another team at the University of Omsk constructed a Russian version for use at schools for gifted children.

In the published version of his John Locke lectures at Oxford, Hintikka in 1973 raised the Dawkins question (see above) for these games. His answer was that one should look to Wittgenstein's language games, and the language games for understanding quantifiers are those which revolve around seeking and finding. In the corresponding logical games one should think of ∃ as Myself and ∀ as a hostile Nature who can never be relied on to present the object I want; so to be sure of finding it, I need a winning strategy. This story was never very convincing; the motivation of Nature is irrelevant, and nothing in the logical game corresponds to seeking. In retrospect it is a little disappointing that nobody took the trouble to look for a better story. It may be more helpful to think of a winning strategy for ∃ in G(φ) as a kind of proof (in a suitable infinitary system) that φ is true.

Later Jaakko Hintikka extended the ideas of this section in two directions, namely to natural language semantics and to games of imperfect information. The name *Game-Theoretic Semantics*, GTS for short, has come to be used to cover both of these extensions.

The games described in this section adapt almost trivially to many-sorted logic: for example the

quantifier $\forall x$, where x is a variable of sort σ, is an instruction for player $\forall$ to choose an element of sort σ. This immediately gives us the corresponding games for second-order logic, if we think of the elements of a structure as one sort, the sets of elements as a second sort, the binary relations as a third and so on. It follows that we have, quite routinely, game rules for most generalised quantifiers too; we can find them by first translating the generalised quantifiers into second-order logic.

4. Modal Semantics

Structures of the following kind give rise to interesting games. The structure *A* consists of a set *S* of elements (which we shall call *states*, adding that they are often called *worlds*), a binary relation *R* on *S* (we shall read *R* as *arrow*), and a family P_1,..., P_n of subsets of *S*. The two players $\forall$ and $\exists$ play a game G on *A*, starting at a state *s* which is given them, by reading a suitable logical formula φ as a set of instructions for playing and for winning.

Thus if φ is P_i, then player $\exists$ wins at once if *s* is in P_i, and otherwise player $\forall$ wins at once. The formulas $\psi \wedge \theta$, $\psi \vee \theta$ and $\neg \psi$ behave as in Hintikka's games above; for example $\psi \wedge \theta$ instructs player $\forall$ to choose whether the game shall continue as for ψ or for θ. If the formula φ is $\Box \psi$, then player $\forall$ chooses an arrow from *s* to a state *t* (i.e. a state *t* such that the pair (*s*, *t*) is in the relation *R*), and the game then proceeds from the state *t* according to the instructions ψ. The rule for $\Diamond \psi$ is the same except that player $\exists$ makes the choice. Finally we say that the formula φ is *true at s in A* if player $\exists$ has a winning strategy for this game based on φ and starting at *s*.

These games stand to modal logic in very much the same way as Hintikka's games stand to first-order logic. In particular they are one way of giving a semantics for modal logic, and they agree with the usual Kripke-type semantics. Of course there are many types and generalisations of modal logic (including closely related logics such as temporal, epistemic and dynamic logics), and so the corresponding games come in many different forms. One example of interest is the computer-theoretic logic of Martin Hennessy and Robin Milner, used for describing the behaviour of systems; here the arrows come in more than one colour, and moving along an arrow of a particular colour represents performing a particular ‘action’ to change the state. In the related ’logic of games’, proposed by Rohit Parikh, games that move us between the states are the subject matter rather than a way of giving a truth definition.

5. Back-and-Forth Games

In 1930 Alfred Tarski formulated the notion of two structures *A* and *B* being *elementarily equivalent*, i.e. that exactly the same first-order sentences are true in *A* as are true in *B*. At a conference in Princeton in 1946 he described this notion and expressed the hope that it would be possible to develop a theory of it that would be ‘as deep as the notions of isomorphism, etc. now in use’ (Hourya Sinaceur ed., "Address at the Princeton University Bicentennial Conference on Problems of Mathematics (December 17-19, 1946), by Alfred Tarski", *Bulletin of Symbolic Logic* **6** (2000): 1-44).

One natural part of such a theory would be a purely structural necessary and sufficient condition for two structures to be elementarily equivalent. Roland Fraïssé, a French-Algerian, was the first to find a usable necessary and sufficient condition. It was rediscovered a few years later by the Kazak logician A. D. Taimanov, and it was reformulated in terms of games by the Polish logician Andrzej Ehrenfeucht. The games are now known as *Ehrenfeucht-Fraïssé* games, or sometimes as *back-and-forth* games. They have turned out to be one of the most versatile ideas in twentieth-century logic. They adapt fruitfully to a wide range of logics and structures.

In a back-and-forth game there are two structures *A* and *B*, and two players who are commonly called Spoiler and Duplicator. (The name is due to Joel Spencer in the early 1990s. More recently Neil Immerman suggested Samson and Delilah, using the same initials; this places Spoiler as the male player ∀ and Duplicator as the female ∃.) Each step in the game consists of a move of Spoiler, followed by a move of Duplicator. Spoiler chooses an element of one of the two structures, and Duplicator must then choose an element of the other structure. So after *n* steps, two sequences have been chosen, one from *A* and one from *B*:

$$(a_0,\ldots,a_{n-1};b_0,\ldots,b_{n-1}).$$

This position is a win for Spoiler if and only if some atomic formula (of one of the forms ‘$R(v_0,\ldots,v_{k-1})$’ or ‘$F(v_0,\ldots,v_{k-1}) = v_k$’ or ‘$v_0=v_1$’, or one of these with different variables) is satisfied by $(a_0,\ldots,a_{n-1})$ in *A* but not by $(b_0,\ldots,b_{n-1})$ in *B*, or vice versa. The condition for Duplicator to win is different in different forms of the game. In the simplest form, EF(*A*,*B*), a play is a win for Duplicator if and only if no initial part of it is a win for Spoiler (i.e. she wins if she hasn't lost by any finite stage). For each natural number *m* there is a game $EF_m(A,B)$; in this game Duplicator wins after *m* steps provided she has not yet lost. All these games are determined, by the Gale-Stewart Theorem. The two structures *A* and *B* are said to be *back-and-forth equivalent* if Duplicator has a winning strategy for EF(*A*,*B*), and *m-equivalent* if she has a winning strategy for $EF_m(A,B)$.

One can prove that if *A* and *B* are *m*-equivalent for every natural number *m*, then they are elementarily equivalent. On the other hand a winning strategy for Spoiler in $EF_m(A,B)$ can be converted into a first-order sentence that is true in exactly one of *A* and *B*, and in which the nesting of quantifier scopes has at most *m* levels. So we have our necessary and sufficient condition for elementary equivalence, and a bit more besides.

If *A* and *B* are back-and-forth equivalent, then certainly they are elementarily equivalent; but in fact back-and-forth equivalence turns out to be the same as elementary equivalence in an infinitary logic which is much more expressive than first-order logic. There are many adjustments of the game that give other kinds of equivalence. For example Barwise, Immerman and Bruno Poizat independently described a game in which the two players have exactly *p* numbered pebbles each; each player has to label his or her choices with a pebble, and the two choices in the same step must be labelled with pebbles carrying the

same number. As the game proceeds, the players will run out of pebbles and so they will have to re-use pebbles that were already used. The condition for Spoiler to win at a position (and all subsequent positions) is the same as before, except that only the elements carrying labels at that position count. The existence of a winning strategy for Duplicator in this game means that the two structures agree for sentences which use at most *p* variables (allowing these variables to occur any number of times).

The theory behind back-and-forth games uses very few assumptions about the logic in question. As a result, these games are one of the few model-theoretic techniques that apply as well to finite structures as they do to infinite ones, and this makes them one of the cornerstone of theoretical computer science. One can use them to measure the expressive strength of formal languages, for example database query languages. A typical result might say, for example, that a certain language can't distinguish between ‘even’ and ‘odd’; we would prove this by finding, for each level *n* of complexity of formulas of the language, a pair of finite structures for which Duplicator has a winning strategy in the back-and-forth game of level *n*, but one of the structures has an even number of elements and the other has an odd number.

There is also a kind of back-and-forth game that corresponds to our modal semantics above in the same way as Ehrenfeucht-Fraïssé games correspond to Hintikka's game semantics for first-order logic. The players start with a state *s* in the structure *A* and a state *t* in the structure *B*. Spoiler and Duplicator move alternately, as before. Each time he moves, Spoiler chooses whether to move in *A* or in *B*, and then Duplicator must move in the other structure. A move is always made by going forwards along an arrow from the current state. If between them the two players have just moved to a state *s*' in *A* and a state *t*' in *B*, and some predicate P_i holds at just one of *s*' and *t*', then Duplicator loses at once. Also she loses if there are no available arrows for her to move along; but if Spoiler finds there are no available arrows for him to move along in either structure, then Duplicator wins. If the two players play this game with given starting states *s* in *A* and *t* in *B*, and both structures have just finitely many states, then one can show that Duplicator has a winning strategy if and only if the same modal sentences are true at *s* in *A* as are true at *t* in *B*.

There are many generalisations of this result, some of them involving the following notion. Let *Z* be a binary relation which relates states of *A* to states of *B*. Then we call *Z* a *bisimulation* between *A* and *B* if Duplicator can use *Z* as a nondeterministic winning strategy in the back-and-forth game between *A* and *B* where the first pair of moves of the two players is to choose their starting states. In computer science the notion of a bisimulation is crucial for the understanding of *A* and *B* as systems; it expresses that the two systems interact with their environment in the same way as each other, step for step. But a little before the computer scientists introduced the notion, essentially the same concept appeared in Johan van Benthem's PhD thesis on the semantics of modal logic (1976).

6. Dialogue Games and Proof-theoretic Semantics

Imagine ∃ taking an oral examination in proof theory. The examiner gives her a sentence and invites her to start proving it. If the sentence has the form

$$\varphi \vee \psi$$

then she is entitled to choose one of the sentences and say ‘OK, I'll prove this one’. (In fact if the examiner is an intuitionist, he may insist that she choose one of the sentences to prove.) On the other hand if the sentence is

$$\varphi \wedge \psi$$

then the examiner, being an examiner, might well choose one of the conjuncts himself and invite her to prove that one. If she knows how to prove the conjunction then she certainly knows how to prove the conjunct.

The case of $\varphi \rightarrow \psi$ is a little subtler. She will probably want to start by assuming φ in order to deduce ψ; but there is some risk of confusion because the sentences that she has written down so far are all of them things to be proved, and φ is not a thing to be proved. The examiner can help her by saying ‘I'll assume φ, and let's see if you can get to φ from there’. At this point there is a chance that she sees a way of getting to φ by deducing a contradiction from ψ; so she may turn the tables on the examiner and invite him to show that his assumption is consistent, with a view to proving that it isn't. The symmetry is not perfect: he was asking her to show that a sentence is true everywhere, while she is inviting him to show that a sentence is true somewhere. Nevertheless we can see a sort of duality.

Ideas of this kind lie behind the dialectical games of Paul Lorenzen. He showed that with a certain amount of pushing and shoving, one can write rules for the game which have the property that ∃ has a winning strategy if and only if the sentence that she is presented with at the beginning is a theorem of intuitionistic logic. In a gesture towards medieval debates, he called ∃ the Proponent and the other player the Opponent. (In the medieval version they are usually Respondens and Opponens.) Almost as in the medieval obligationes, the Opponent wins by driving the Proponent to a point where the only moves available to her are blatant self-contradictions.

Lorenzen claimed that the rules of his games could be justified on a pre-logical basis, and so they formed a foundation for logic. Unfortunately any ‘justification’ involves a convincing answer to the Dawkins question, and this Lorenzen never provided. For example he spoke of moves as ‘attacks’, even when (like the examiner's choice at $\varphi \wedge \psi$ above) they look more like help than hostility. To repair Lorenzen's omission, one certainly needs to distinguish between different stances that a person might take in an argument: stating, assuming, conceding, querying, attacking, committing oneself. Whether it is really possible to define all these notions in a pre-logical way is a moot point. But perhaps this is unimportant. A more positive view is that this kind of refinement serves to link Lorenzen's dialogues to informal logic, and especially to the research that aims to systematise the possible structures of sound informal argument.

In any case, Lorenzen's games stand as an important paradigm of what recent proof theorists have called *semantics of proofs*. A semantics of proofs gives a ‘meaning’ not just to the notion of being provable, but to each separate step in a proof. It answers the question ‘What do we achieve by making this particular move in the proof?’ During the 1990s a number of workers at the logical end of computer science looked for games that would stand to linear logic and some other proof systems in the same way as Lorenzen's games stood to intuitionist logic. Andreas Blass, and then later Samson Abramsky and colleagues, gave games that corresponded to parts of linear logic, but at the time of writing we don't yet have a perfect correspondence between game and logic. This example is particularly interesting because the answer to the Dawkins question should give an intuitive interpretation of the laws of linear logic, a thing that this logic has badly needed. The games of Abramsky et al. tell a story about two interacting systems. But while he began with games in which the players politely take turns, Abramsky's more recent work allows the players to act ‘in a distributed, asynchronous fashion’, taking notice of each other only when they choose to. These games are no longer in the normal format of logical games, and their real-life interpretation raises a host of new questions.

7. Other Model-theoretic Games

The logical games in this section are mathematicians' tools, but they have some conceptually interesting features.

Forcing games

Forcing games are also known to descriptive set theorists as *Banach-Mazur games*; see the references by Kechris or Oxtoby below for more details of the mathematical background. Model theorists use them as a way of building infinite structures with controlled properties. To sketch the idea, imagine that a countably infinite team of builders are building a house *A*. Each builder has his or her own task to carry out: for example to install a bath or to wallpaper the entrance hall. Each builder has infinitely many chances to enter the site and add some finite amount of material to the house; these slots for the builders are interleaved so that the whole process takes place in a sequence of steps counted by the natural numbers.

To show that the house can be built to order, we need to show that each builder separately can carry out his or her appointed task, regardless of what the other builders do. So we imagine each builder as player ∃ in a game where all the other players are lumped together as ∀, and we aim to prove that ∃ has a winning strategy for this game. When we have proved this for each builder separately, we can imagine them going to work, each with their own winning strategy. They all win their respective games and the result is one beautiful house.

More technically, the elements of the structure *A* are fixed in advance, say as a_0, a_1, a_2 etc., but the properties of these elements have to be settled by the play. Each player moves by throwing in a set of atomic or negated atomic statements about the elements, subject only to the condition that the set

consisting of all the statements thrown in so far must be consistent with a fixed set of axioms written down before the game. (So throwing in a negated atomic sentence $\neg\varphi$ has the effect of preventing any player from adding φ at a later stage.) At the end of the joint play, the set of atomic sentences thrown in has a canonical model, and this is the structure *A*; there are ways of ensuring that it is a model of the fixed set of axioms. A possible property P of *A* is said to be *enforceable* if a builder who is given the task of making P true of *A* has a winning strategy. A central point (due essentially to Ehrenfeucht) is that the conjunction of a countably infinite set of enforceable properties is again enforceable.

The name ‘forcing’ comes from an application of related ideas by Paul Cohen to construct models of set theory in the early 1960s. Abraham Robinson adapted it to make a general method for building countable structures, and Martin Ziegler introduced the game setting. More recently Robin Hirsch and Ian Hodkinson have used related games to settle some old questions about relation algebras.

Forcing games are a healthy example to bear in mind when thinking about the Dawkins question. They remind us that in logical games it need not be helpful to think of the players as opposing each other.

Cut-and-choose games

In the traditional cut-and-choose game you take a piece of cake and cut it into two smaller pieces; then I choose one of the pieces and eat it, leaving the other one for you. This procedure is supposed to put pressure on you to cut the cake fairly. Mathematicians, not quite understanding the purpose of the exercise, insist on iterating it. Thus I make you cut the piece I chose into two, then I choose one of those two; then you cut this piece again, and so on indefinitely. Some even more unworldly mathematicians make you cut the cake into countably many pieces instead of two.

These games are important in the theory of definitions. Suppose we have a collection *A* of objects and a family *S* of properties; each property cuts *A* into the set of those objects that have the property and the set of those that don't. Let ∃ cut, starting with the whole set *A* and using a property in *S* as a knife; let ∀ choose one of the pieces (which are subsets of *A*) and give it back to ∃ to cut again, once more using a property in *S*; and so on. Let ∃ lose as soon as ∀ chooses an empty piece. We say that (*A*,*S*) has *rank* at most *m* if ∀ has a strategy which ensures that ∃ will lose before her *m*-th move. The rank of (*A*,*S*) gives valuable information about the family of subsets of *A* definable by properties in *S*.

Variations of this game, allowing a piece to be cut into infinitely many smaller pieces, are fundamental in the branch of model theory called *stability theory*. Broadly speaking, a theory is ‘good’ in the sense of stability theory if, whenever we take a model *A* of the theory and *S* the set of first-order formulas in one free variable with parameters from *A*, the structure (*A*,*S*) has ‘small’ rank. A different variation is to require that at each step, ∃ divides into two each of the pieces that have survived from earlier steps, and again she loses as soon as one of the cut fragments is empty. (In this version ∀ is redundant.) With this variation, the rank of (*A*,S) is called its *Vapnik-Chervonenkis dimension*; this notion is used in computational learning theory.

Games on the tree of two successor functions

Imagine a tree that has been built up in levels. At the bottom level there is a single root node, but a left branch and a right branch come up from it. At the next level up there are two nodes, one on each branch, and from each of these nodes a left branch and a right branch grow up. So on the next level up there are four nodes, and again the tree branches into left and right at each of these nodes. Continued to infinity, this tree is called the *tree of two successor functions* (namely left successor and right successor). Taking the nodes as elements and introducing two function symbols for left and right successor, we have a structure. A powerful theorem of Michael Rabin states that there is an algorithm which will tell us, for every monadic second-order sentence φ in the language appropriate for this structure, whether or not φ is true in the structure. ('Monadic second-order' means that the logic is like first-order, except that we can also quantify over sets of elements -- but not over binary relations on elements, for example.)

Rabin's theorem has any number of useful consequences. For example Dov Gabbay used it to prove the decidability of some modal logics. But Rabin's proof, using automata, was notoriously difficult to follow. Yuri Gurevich and Leo Harrington, and independently Andrei Muchnik, found much simpler proofs in which the automaton is a player in a game. This result is one of several that connect games with automata.

Replication

The basic idea of replication has a long history in biology, beginning with the traditional distinction between homocatalysis and heterocatalysis and then later between transcription and translation. The basic distinction that these pairs of terms were designed to indicate is between like producing like (homocatalysis and transcription) and like producing unlike (heterocatalysis and translation). The paradigm example of this distinction is the contrast between genes and organisms. Genes perform two functions. They make other genes and, by means of the developmental process, they help produce organisms and their phenotypic traits (for a recent discussion of these two processes at the molecular level, see Rebek 1994 and Cook 1999).

As pervasive as this terminology has been, it engendered very little controversy until Richard Dawkins introduced the distinction between replicators and vehicles in his *The Selfish Gene* (1976). For his purposes Dawkins found the contrast between genes and organisms too restrictive. Everyone agrees that genes are replicators, but genes may not be the only replicators. Perhaps more inclusive entities than single genes might also function as replicators. At the very least, this possibility should not be defined out of existence. Hence, Dawkins adopted “replicator” as a more inclusive term than “gene.” He also introduced the term “vehicle” for those entities produced by replicators that help these replicators increase in numbers by interacting effectively with their environments. This distinction can be expressed in terms of either entities or processes. According to Dawkins replicators function in replication, while vehicles function in environmental interaction.

A long-standing dispute in evolutionary biology concerns the levels at which selection can occur (Brandon 1996, Keller 1999). As it turns out, there is no one process termed “selection.” Instead there are two -- “replication” and “environmental interaction”. Some authors see this dispute as concerning the levels at which replication can take place. Dawkins argues that replication in *biological* evolution occurs exclusively at the level of the genetic material. Hence, he is a gene replicationist. Other authors take the levels of selection dispute to concern environmental interaction and insist that environmental interaction can take place at a variety of levels from single genes, cells and organisms to colonies, demes and possibly entire species. Organisms certainly interact with their environments in ways that bias the transmission of their genes, but then so do entities that are both less inclusive than entire organisms (e.g., sperm cells) and more inclusive (e.g., beehives).

The term “replication” refers first and foremost to like producing like. The nature of this process of replication and the objections to it are the main topics of this entry. Genes are self-replicating molecules. Some critics interpret this claim to be asserting that a strand of DNA placed on a glass slide might all on

its own start replicating. Of course, no one has ever held such a nonsense view. Genes replicate themselves but only with the aid of highly complicated molecular machinery. Too often, however, the importance of this machinery goes unnoticed. To be sure, when we make copies on a Xerox machine, we are interested in the texts, figures or just scrawls that appear on these sheets of paper. We are not interested in how the Xerox machine works, even if it does *all* the work.

Another issue arises when replication is analyzed in terms of information. Numerous mechanisms exist for passing on information from one replicator to another. Sometimes the material in which the information is encoded gets passed on; sometimes not. For example, in the commonest sort of transcription in biology, replication is accompanied by the transmission of a substantial amount of physical material. However, in other sorts of information transfer, little or no matter is passed on. In this case, replication via DNA is aberrant, not typical. Other critics object to any use of terms associated with human languages to characterize biological replication. Talk about the genetic code is at best heuristic, at worst totally inappropriate. However, the major problem with treating replication in biological contexts is that we do not have an analysis of "information" and related terms up to the job.

As mentioned earlier, genes have two functions. One is replication. The other is the production of organisms and their phenotypic traits. The connections between genes and organisms (development) are notoriously controversial. The vast majority of literature on the topic of replication, environmental interaction and selection concerns the complexities involved in describing development. Does it make sense to refer to the "gene for eye color" or the "gene for homosexuality"? However, the topic of this contribution is replication, not development. In replication, like produces like, genes producing genes and, more generally, replicators producing replicators. Making sense of this topic is intimidating enough without introducing the relation between replication and environmental interaction. Unfortunately, replication cannot be explicated adequately without at least touching on development and its constituent difficulties. For example, if replication were simply the passing on of structure largely intact without any subsequent translation, we would not be tempted to employ terms such as "information" in connection with it.

---

1. The Conceptual Grip of Genes and Organisms

Those of us who are attempting to provide a more general analysis of “selection” try to free ourselves from the conventional way of viewing this process. For example, according to the Central Dogma of molecular biology, information can be transferred from nucleic acid to nucleic acid or from nucleic acid to proteins. It cannot be transferred from protein to protein or from proteins to nucleic acid. This asymmetry results from nucleic acids exhibiting what might be termed “potential information” while proteins do not. Given a particular stretch of DNA, it can give rise to a variety of proteins, depending on various environment factors. In a particular interaction, a particular protein will be produced. This protein will be only one of the numerous proteins possible given that stretch of DNA. In the translation of potential information into an actual protein, lots of information is lost. Hence, it is no longer available to be read back into the DNA that produced it.

But what if information flow occurs without the participation of genes? For example, from season to season a butterfly feeds on and lays her eggs on the same sort of nasty tasting host plant. In the process she transfers the nasty taste of the host plant to herself and to her progeny. Then her progeny does the same. This looks very much like information being transferred but not via the genes. Granted, genes play several important roles in this process but not in the transference of information. As another example, what if proteins served as templates for other proteins? We would have copying but nothing that might be termed a “genetic code” (Godfrey Smith 2000). The point of the preceding examples is to indicate how closely we are tied to traditional ways of viewing replication and translation. For example, just about everyone assumes that development is the only relation between replication and environmental interaction. Development is one possible relation between replicators and environmental interaction but not the only one. Freeing ourselves from the perspective of genes, organisms and development is easier said than done. It is too easy to slide back into “old think.”

In this article fundamentally different perspectives are introduced and compared - so fundamental that they deserve to be termed “metaphysical.” Although the weight of evidence can be brought to bear on these alternative formulations, it is rarely decisive. Rather the deciding factor is how well these different perspectives organize this data. What impact on our understanding of biological phenomena does switching to the Gene’s Eye view produce? Does extending the phenotype hurt or help? How about extending the notion of replication? Do these more general concepts facilitate the formation of a general analysis of replication that applies at the very least to gene-based biological evolution but also to selection in other contexts? Any answer to these questions entails a strange mix of science and philosophy.

I begin with Dawkins’ analysis because historically his writings gave rise to the present-day controversy over replication and replicators. The first issue concerns disagreements over the proper definition of “replicator.” Dawkins argues that genes and only genes function as replicators in biology. He also introduces vehicles as the entities that aid genes in their quest to become more prevalent, but gradually he reduces the role of vehicles until it is all but nonexistent. I then to proceed to evaluate the various criticisms of genes as replicators and Dawkins’ extended phenotype. Can various elements of the immune

system function as replicators? How about conceptual change? Can it be profitably viewed as a selection process? The idea of *copying* is essential to this discussion. I then turn to Developmental Systems Theory and the attempt to extend the replicator. Genes are replicators, but possibly they are not the only replicators. Finally, I discuss all too briefly the role of *information* in replication.

2. Dawkins on Replicators and Vehicles

For Dawkins selection results from an interplay between replicators and vehicles. Replicators produce copies of themselves, but they also produce entities that interact with their environments in such a way that replication is differential. Some replicators are passed on more profusely than others. For Dawkins, genes are the sole replicators in biological evolution. They are important in a second sense as well. As fascinating as all the complex adaptations that have arisen through selection may be, the results of this process matter in selection only if they are reflected in the content of their respective replicators. Dawkins is frequently (and inaccurately) castigated for being a genetic determinist, as if he thought that genes are sufficient to produce phenotypic traits, but he is aware of the crucial role that an organism's environment, including other organisms, plays in selection. A gene all by itself never did anything.

In Dawkins' early writings, replicators and vehicles played different but complementary and equally important roles in selection, but as Dawkins honed his view of the evolutionary process, vehicles became less and less fundamental. Initially, Dawkins was content to dethrone the organism from its pride of place in biology. It is an important focus of environmental interaction, but other entities, both below and above the organismic level, can also function as vehicles. In later writings Dawkins goes even further and argues that phenotypic traits are what really matter in selection and that they can be treated independently of their being organized into vehicles. More than that, features such as spider webs should be viewed as part of a spider's phenotype. Hence, Dawkins chose as the title of his second book *The Extended Phenotype* (1982a).

From the start Dawkins acknowledged that entities at a variety of levels can function as vehicles. The issue for Dawkins is replication, and according to Dawkins, genes and only genes can function as replicators in biological evolution. How big these genetic units are depends on such things as the prevalence of sex, the frequency of crossover and the intensity of selection. "If there were sex but no crossing-over, each chromosome would be a replicator, and we should speak of adaptations as being for the good of the chromosome. If there is no sex we can, by the same token, treat the entire genome of an asexual organism as a replicator. But the organism itself is not a replicator" (Dawkins 1982a:95).

Dawkins presents two reasons for organisms not being able to function as replicators. The first is the one he uses to delineate evolutionary genes. As in the case of long stretches of DNA, organisms are too easily and frequently broken up to be considered units of replication. A second reason why whole organisms cannot function as replicators is that they cannot pass on changes in their structure. Phenotypic change may result in phenotypic change (as in bad tasting butterflies), but these changes do not find their way to the genetic material. Like it or not, Lamarckian inheritance does not occur. The amount of DNA that counts as a replicator certainly varies, but according to Dawkins, nothing more inclusive than the genetic

material functions as replicators in biological evolution.

Dawkins never lost his fascination with vehicular adaptations, a fascination that his critics denigrate as Panglossian adaptationism. He fills his books with adaptationist scenarios, some more firmly supported by data than others, but from the perspective of the structure of evolutionary theory, replicators are much more important than vehicles. For example, Dawkins argues at some length that adaptations are always for the good of replicators, not vehicles. Vehicles *exhibit* these adaptations, but ultimately all adaptations must be *explicable* in terms of changes in gene frequencies. Thus, it comes as no surprise when Dawkins (1994:617) proclaims that he "coined the term 'vehicle' not to praise it but to bury it." As prevalent as organisms might be, as determinate as the causal roles that they play in selection are, reference to them can and must be omitted from any perspicuous characterization of selection in the evolutionary process. Dawkins is far from a genetic *determinist*, but he is certainly a genetic *reductionist*. Whether reductionism itself is good or bad is a moot question (Van Regenmortel and Hull 2002).

3. Replicators and Genes

Although Dawkins finds it desirable to replace genes with replicators in his general characterization of the evolutionary process, he says very little about this more general notion in his *The Selfish Gene*. Instead he discusses the special case of genes as replicators. The primacy of the genetic perspective in the characterization of replicators is one of the chief weaknesses not only in Dawkins' discussions but also in the work of his successors -- including this one. We claim to be providing a general notion of replication, adequate to handle all different sorts of replication, when too often we are simply reading peculiarities of genetic replication into our general analysis of replication.

According to Dawkins, replicators have three basic properties - longevity, fecundity and copying-fidelity. Longevity means longevity in the form of copies. No gene as a physical body lasts all that long. In mitosis, a gene loses half of its substance at each replication. What endures is not the entity itself but the information incorporated in its structure. It is this information that is copied with such high fidelity. Mutations do occur but at very low frequencies. Even so, in some organisms mutation rates must be too high because mechanisms have evolved that search out and repair such errors.

The main source of variation in genes, however, is not mutation but crossover. Pairs of homologous chromosomes line up next to each other at meiosis, crossover and recombine. For stretches of DNA in which different alleles exist, the result can be a change in information. Quite obviously, the shorter the stretch of DNA involved, the less likely that crossover will occur and the message changed. Dawkins appeals to such dismantling of entities to argue against organisms functioning as replicators. In sexual organisms, organisms themselves are torn apart and reassembled each generation. If long stretches of DNA lack the necessary identity by descent to function as replicators, then sexual organisms certainly lack it. However, some other explanation has to be provided for asexual organisms because they pass on their overall structure largely unchanged from generation to generation.

Dawkins bypasses classical Mendelian genes and even molecular genes to adopt G. C. Williams'

conception of evolutionary genes as the fundamental units of natural selection. Dawkins (1976:30) defines evolutionary genes as "any portion of chromosomal material which potentially lasts for enough generations to serve as a unit of natural selection." The limits of these genes need not be absolutely sharp. Nor must all genes be of the same length. The greater the selection pressure, the smaller the gene. At bottom selection takes place between alternative alleles residing at the same locus. "As far as a gene is concerned, its alleles are its deadly rivals, but other genes are just a part of its environment, comparable to temperature, food, and predators, or companions" (Dawkins 1976:40). Alleles cannot cooperate with each other; only compete. That is where "selfish" in the "selfish gene" comes in.

According to Dawkins (1976:95), the selfish gene is not just one physical bit of DNA. It is "all replicas of a particular bit of DNA, distributed throughout the world." Hence, genes do not form classes of spatiotemporally unrelated individuals but trees. They must be replicas. But being a replica is not enough. The linear repetition of the "same gene" in the form of several hundred copies is quite common. These replicas, however, do not reside at the same locus. As identical in structure as these genes may be, they do not compete with each other in the way that alleles at the same locus can. In the simplest and most basic sense, alleles compete with alternative alleles at the same locus. Any other sorts of competition and cooperation are merely extrapolations from this fundamental sense of allelic competition. Even though genes may cooperate with each other in very complicated ways in embryological development, in replication they can be treated as "separate and distinct." In development the effects of genes blend. In replication replicators do not blend.

Dawkins introduced the general notions of replicator and vehicle so that selection need not be limited exclusively to gene-based biological evolution. However, as the preceding discussion indicates, his later revisions to his general theoretical outlook were influenced strongly by the traditional perspective of genes and organisms. Genes contain the information necessary to produce organisms and their adaptations. Genes "ride around" in and "guide" organisms. As Dawkins describes them, vehicles are relatively discrete entities that "house" replicators and which can be regarded as machines programmed to preserve and propagate the replicators that ride inside them. Although these terms may be appropriate for the relations between genes and organisms, they interfere with a more general analysis of replication and selection. What really matters in selection is that entities at various levels of organization interact with their environments in such a way that the relevant replicators increase in relative frequency. The actual causal chain that connects replicators and vehicles need not be limited to development.

For example, Dawkins argues at some length that genes and only genes can function as replicators in biological evolution. He goes on to add that "all adaptations are for the preservation of DNA; DNA itself just is" (Dawkins 1982b:45). But DNA itself exhibits adaptations. Anyone who has spent much time examining the molecular structure of DNA soon realizes that it is adapted to replicate. In addition, the proliferation of junk DNA and meiotic drive are two examples in which the only phenotypes that matter are phenotypic characteristics of genes (Brandon 1996:133; Sterelny, Smith and Dickison 1996:388). Dawkins' characterizations of replicators, vehicles and the relations between the two are too closely tied to genes, organisms and development. DNA can certainly replicate itself, but it can also function as a "vehicle" even though it cannot code for, ride around in or direct itself. In sum, a more general characterization of selection is needed, a characterization that does not assume that the only causal

connection between replicators and vehicles is development.

4. Memes and the Immune System

Initially Dawkins" discusses only one example of replication that goes beyond gene-based biological evolution - memetic change. Later he adds the immune system. Does replication play the same role in other sorts of selection that it plays in gene-based biological evolution? The reaction of the immune system to antigens is closest to the standard biological example of replication and selection. Genes are the primary replicators, but these genes are somatic, not germ-line. Certainly immune systems arose through the same process as other functional systems. The basic structure of the human immune system is "built into our genes," and the only genes that count in evolution are the one that we received from our ancestors and can subsequently pass on to our progeny. In Dawkins' terminology, the genes that code for our immune system are active, germ-line replicators.

However, the genes that function in the reaction of the immune system to antigens have two peculiarities. First, they incorporate mechanisms designed to produce very high frequencies of mutation, and second, none of the genes involved in the functioning of the immune system are germ-line. The genes that give rise to B-cells for instance are designed to mutate extensively until one of these cells identifies an invader as foreign. It then proliferates extensively as it attacks the invader. As an organism matures, it accumulates more and more of the B-cells that have been successful in its past. More than this, as the process of proliferation continues, the strength of the affinities to binding sites increases. Initially the primary antibodies almost always exhibit a weak affinity for their targets, but as the reaction to the antigen continues, these affinities become stronger.

Within the confines of a single organism, the reaction of the immune system to antigens has all the characteristics of selection processes, but when the organism dies all of these adaptations are lost. In some species, females pass on not only the genes for the basic structure of their immune systems but also some of the machinery that past invasions of antigens have produced in her. However, these cells are rapidly removed from the offspring as it develops its own immune system. The reaction of the immune system to antigens departs from gene-based selection in biological evolution in two ways. First, from the organismal perspective, the genes that function in protecting an organism from invaders are not germ-line. They are somatic. Second, the relevant mutation rates are much, much higher in the immune system than in ordinary gene-based selection. Instead of mechanisms existing to discover mutations and repair them, mechanisms exist that encourage mutations - massively so. If the functioning of the immune system is to count as selection, then some changes must be made. One possibility is to clarify what counts as a "germ-line" replicator and a rejection of the notion that extremely low mutation rates are inherent in all selection processes.

The modifications needed to include both gene-based selection in ordinary biological evolution and the reaction to the immune system are relatively "minor." Such is not the case with Dawkins' second example - memetic evolution. Several apparent differences exist between it and the previous examples of replication and selection. Numerous critics have developed a cottage industry engaged in listing all the

differences that exist between biological evolution, on the one hand, and social-cultural-conceptual evolution on the other (henceforth, SCC). For example, Dawkins (1976) admits that he is on shaky ground when it comes to the high copying fidelity required of replicators. Memes seem to get changed much more frequently than genes. However, if differences in copying fidelity are enough to preclude memetic evolution from being a genuine case of selection, then the immune system must also be rejected. Mutation rates are much higher in the production of B-calls than in any area of SCC no matter how speed is calculated.

In general, the standards used to evaluate memetic evolution are much higher than those used to evaluate any other sort of selection. Time and again an overly idealized view of Mendelian genetics is contrasted to a much more realistic view of SCC change. So the story goes, one problem with memes is that they do not have discrete boundaries, do not all come in the same size, and in their functioning are strongly influenced by their environments. Genes, so the critics claim, have sharp boundaries, are all of the same size, and are immune to environmental influences. If memetic evolution is to be evaluated fairly, the same level of criticism must be applied to all putative examples of selection from gene-based selection in biological evolution and the reaction of the immune system to antigens to the development of the central nervous system and social learning (Hull, Langman and Glenn 2001).

Dawkins (1976) also places considerable emphasis on human brains as the “vehicles” for memetic evolution. He defines “meme” as an entity capable of being transmitted from one brain to another. Computers are also plausible vehicles for memes. Dawkins- discussion of memes is, once again, marred by the pervasiveness of the gene-organism perspective. For example, he defines “replicator” in terms of transmission of information - memes leaping from brain to brain or from brains to computers and back again. But memes do not leap from brain to brain or from computer to computer. Their content is transmitted in a variety of ways, including books, audiotapes, conversations and the like. As much as the physical basis changes, the message remains sufficiently unchanged. All instances of this message are equally memes, not just the ones residing in human brains and computers.

All the objections to the gene-meme analogy to one side, Dawkins (1976:211) finds the chief difference between genetic and memetic change is that biological evolution is at bottom a war between alleles residing at the same locus. “Memes seem to have nothing equivalent to chromosomes and nothing equivalent to alleles.” First, the usual depiction of alleles residing at the same locus on homologous chromosomes so central to Mendelian genetics is an over simplification, but more importantly, for at least half of life on earth, replication and selection took place in the absence of chromosomes, meiosis and the like. If gene-based biological evolution took place for so long in the absence of the Mendelian apparatus and still does so in many extant organisms, then just possibly we should not demand that memetic evolution proceed by this very special and possibly aberrant sort of inheritance. The cost of meiosis remains a serious problem in ordinary biological evolution. Demanding that SCC evolution incorporate this same highly problematic element in its own makeup seems strange in the extreme. If we are to develop a general analysis of selection, then we must distinguish between essential and contingent features of this process.

Numerous evolutionary biologists question how fundamental to selection the perspective of alleles at a

locus actually is. Everyone certainly says that evolution is changes in gene frequencies. However, many do not go on to add that evolution is *nothing but* changes in gene frequencies. When one looks at the work of evolutionary biologists, one discovers that it involves much more than changes in gene frequencies. Selection in meme-based evolution must be fleshed out. It remains to be seen how different well-worked-out versions of SCC theory will differ from more familiar forms of selection. And where they differ, it does not follow automatically that the meme-based theory must be modified. One might well change the traditional gene selectionist view of biological evolution. Selection in gene-based theories of evolution was worked out first, but historical precedence does not entail conceptual priority.

5. The Extended Replicator

The discussion thus far has involved criticisms of Dawkins' notion of genes and replication. Dawkins' critics think that genes play too important of a role in his notion of replication. Replication, so they argue, can occur at other levels of organization as well. Just as Dawkins extended the notion of the phenotype, these authors propose to make the notion of replicators more general as well - to extend the replicator so to speak. Dawkins introduced his *Extended Phenotype* conception for two reasons. First, he wanted to extend the notion of a "phenotypic trait." The sort of nest that a bird builds or the song that it sings can count as phenotypic traits just as much as the shape of its bill. Second, Dawkins wanted to break the hold that organisms have over how we conceptualize the living world. Traits do tend to come bundled into reasonably discrete entities, but for making inferences about the evolutionary process, traits can be treated as separate and distinct. However, as he proceeded, Dawkins eventually decided that extending the phenotype was not enough. He had to bury it. All sorts of fascinating mechanisms to one side, what really matters in selection takes place at the level of replicators.

Although such critics of Dawkins as Sterelny *et al*. (1996) decline to join with Dawkins in his demotion of environmental interaction, they do agree with him that replicators are special. They play a special role in development. However, they do not limit replicators to genes even in biological evolution. Sterelny *et al*. (1996) propose to extend the replicator to include nonstandard entities. For example, the sort of burrow that a particular organism digs is influenced by its genetic makeup, but if these burrows are used over and over again, characteristics of these burrows can themselves be viewed as replicators. The effects of these burrows get passed on from generation to generation but not via the genes.

As more and more nongenetic replicators are acknowledged, Dawkins' Gene's Eye view begins to gradate into the conception of the Extended Replicator. These two views are so general that any case that can be described in one can be redescribed in the other. Differences lie in ease of description. According to Sterelny et al., the burrows that some organisms dig can function as replicators - extended replicators - while Dawkins portrays them as instance of extended phenotypes. The contrast is between selfish burrows and selfish genes for burrowing.

Starting with Oyama's *The Ontogeny of Information* (1985), a view of biological evolution has arisen that emphasizes development (see also Griffiths and Gray 1994, Oyama 2000). In the 19th century development was an extremely active research program. The next great discoveries in biology were going

to be in the area of development. Such was not to be. First, evolutionary biology and then genetics took over biology, and they did so while avoiding development. Everyone knew that development was central to both evolution and reproduction, but no one could see how to integrate the masses of developmental data available into the emerging synthesis of evolutionary biology and genetics. As a result, development was left out of the New Synthesis. Considering how central development actually is in biology, the advances made while ignoring it are staggering.

Even so, developmental biology continued on its course until at long last we seem to understand development well enough to begin integrating it into the rest of biology. On the most conservative view, current versions of evolutionary theory can remain largely unchanged as development is grafted onto them. On a second view, both perspectives are likely to require some modification to bring off this integration. Our understanding of development may have to be modified, but so too for evolutionary theory. Finally, at the other extreme, development will all but replace evolutionary theory. In their more exuberant moments, advocates of Developmental Systems Theory (hereafter DST) seem to be claiming just that. Just as some molecular biologists think that molecular biology is rapidly replacing all the rest of biology, advocates of DST argue that developmental theories will simply replace current versions of evolutionary theory.

On the DST view, genes have no privileged role in repeated cycles of development. In fact, no element of the developmental matrix plays any privileged causal role - not genes, not organisms, not the environment, not anything. Everything counts equally as a resource, albeit in particular situations certain resources will play more important roles than other resources. In rejecting any privileged role for genes, advocates of DST are especially skeptical of one particular role supposedly played by genes - the transmission of information. According to some, information is central to developmentalism, but genes are not the only mechanisms for information transfer. According to others, information plays no role in the emerging developmentalist perspective. The developmental system as a whole is the unit of selection - the replicator.

In the continuing debate over DST versus traditional theories of evolutionary biology, Sterelny *et al*. (1996) hold a fairly conservative position. They agree with the developmentalists that genes play no privileged role in the development of phenotypes from genotypes. Genes play a role in this process, simply not a *privileged* role. Genes can serve as a causal bridge from phenotype to phenotype, but other entities can do so as well. Genes are not the only replicators in biological evolution. The repeated cycles in inheritance include many different sorts of constancies and repetitions - genes, cellular machinery, phenotypic traits including behaviors, and social structures. Information remains central to selection processes, but genes are not the only carriers of such information. Genes predict phenotypic characters only in the same sense that environmental factors predict them.

Both Dawkins (1976) and Hull (1980) distinguish between replicators and vehicles (or interactors). To the questions surrounding these two sorts of entities, Lloyd (1992) adds two more - who “owns” adaptations and who “benefits” from selection? In the previous literature, authors seem to assume a greater concordance in the answers to these four questions than can be justified. Some biologists argue that those entities that exhibit a particular adaptation are the beneficiaries of the selection process that

resulted in these adaptations. Dawkins disagrees. Such adaptations function only as intermediaries in a much more fundamental process - the spreading of copies of particular alleles. These surviving alleles are the long-term beneficiaries of selection processes. Sterelny *et al*. argue that replicators and only replicators are the beneficiaries of adaptations, keeping in mind that they count entities more inclusive than genes as replicators.

With respect to the version of replication formulated by Sterelny *et al*. (1996), both copying and biofunction are crucial. Copying is quite obviously a causal phenomenon, but not any old causal connection will do. Similarity of copies is necessary but not sufficient. These copies must be copies of copies. One copy must produce another copy and that copy produce still another copy and so on. For one entity to be a copy of another, it must be the output of a process whose biofunction is to conserve function. The function of copying is to produce from one token another token which is similar in the relevant respects. Genes fit this definition, but so do lots of examples of nongenetic transmission; e.g., habitat stability resulting from nest site imprinting, the song that a bird learns, various micro-organism symbionts, not to mention SCC transmission.

6. Information

The language of “codes” and “information” flows easily enough with respect to replication. Transcription, translation, punctuation, redundancy, synonymy, editing, proofreading, errors, repairing of errors, messages, copies, and information all sound natural enough. This ease of expression supports the contention that selection plays the same role in SCC evolution as it does in gene-based biological evolution. Some authors argue that both processes count as languages in the same sense of “language.” All the problems listed for treating gene-based biological evolution as a language are simply replicated in ordinary languages. If the genetic code is not a code, then neither is the Morse code or English for that matter. Differences of degree exist but not differences in kind. For example, mutation rates are very low in gene-based biological evolution, moderate in SCC evolution and massive with respect to the immune system. Concurrent variation is extensive in the immune system, greatly reduced in both gene-based biological evolution and SCC evolution, and reduced even further in operant learning.

The literature dealing with information is both extensive and factious. Several different formal analyses of information can be found and very little agreement about which analysis is best for which subjects. On one point these scholars tend to agree - cybernetic information and communication-theoretic information will not do for replication in biological contexts. The best bet is semantic information [Sterelny (2000), Godfrey-Smith (2000) and Sarkar (2000)]. The trouble is that no widely accepted version of semantic information exists. Winnie (2000) distinguishes between Classical and Algorithmic Information Theory and opts for a revised version of the Algorithmic Theory. But once again, the problem is that no such formal analysis currently exists. In the face of all this disagreement and unfinished business, biologists such as Maynard Smith (2000) maintain either that informal analyses of “information” are good enough or that some future formal version of information theory will justify the sorts of inferences that they make. For now, the most likely conclusion is that no version of information theory as currently formulated can handle “information” as it functions in biology (see Griffiths 2001 for further discussion).

7. Conclusion

In general the authors who have concerned themselves with the role of replication in selection strive to liberate our thinking from the hold that genes and organisms have over us. To the extent that replication can be separated off from development, it plays a central role in selection processes of all sorts, including traditional gene-based biological evolution, the reaction of the immune system to antigens and possibly even SCC evolution. In reaction to all sorts of nonstandard examples of replication, Dawkins is driven to extend the phenotype. In reaction to DST some critics of Dawkins extend the replicator as well. Replicators include genes, memes and even entities that are commonly thought of as parts of an organism's phenotype or environment. Some authors argue that replication in this extended sense is necessary for selection; others that it is not. Selection can occur in the absence of replication. Still others maintain that all of these biological phenomena are best explained without any reference to such traditional notions as replication, environmental interaction, selection, evolution, etc., in terms of DST.

Mental Illness

Psychiatry involves theories of the mind, theories of the causes of mental disorders, classification schemes for those disorders, research about the disorders, proven treatments and research into new treatments, and a number of professions whose job it is to work with or on behalf of people with mental disorders. The philosophical study of psychiatry discusses conceptual, ethical, metaphysical, social, and epistemological issues that arise in all these aspects of psychiatry Central to this study is the nature of mental illness.

The connection between philosophical issues in the study and treatment of mental illness and these other areas of philosophy is in many cases obvious. For example, it takes little thought to see how the question of when and how people with mental disorders are responsible for their actions is connected with the insanity defense in law, and the more general debate over the justification of punishment. Similarly, it is clear how studying the historical growth of the idea of madness and changes in the way societies treat those they classify as mad helps us assess claims that psychiatry today is a form of social control, and further, whether social control is a legitimate function for psychiatry.

The philosophical investigation of the nature of mental illness is therefore relevant to many other areas of philosophy. While there is no sharp divide between the philosophical discussion of the nature of mental illness and the wider philosophical discussion of psychiatry, we can focus on three major issues that have preoccupied the philosophical literature.

1. Does Mental Illness Exist

The English-speaking world has not always used medical language to describe the behavior we now label

as symptomatic of mental illness or mental disorder. Descriptions were sometimes framed in quite different terms, such as possession. What we now call mental illness was not always treated as a medical problem. Non-English-speaking nations in the West have had changes in their linguistic usage and their treatment of the mentally ill roughly parallel to Anglophone countries. Anthropological work in non-Western cultures suggests that there are many cases of behavior that psychiatry would classify as symptomatic of mental disorder, which are not seen within their own cultures as signs of mental illness. Indeed, other cultures may not even have a concept of mental illness that corresponds even approximately to the Western concept.

The mainstream view in the West is that the changes in our description and treatment of mental illness are a result of our increasing knowledge and greater conceptual sophistication. On this view, we have conquered our former ignorance and now know that mental illness exists, even though there is a great deal of further research to be done on the causes and treatment of mental illness. However, there are some thinkers who have challenged this mainstream view. Some have argued for a relativist view, that the reality of mental illness is not an absolute transcultural fact. The relativist view would have to be that statements about the existence of mental illness can be true in some cultures and false in other cultures.

A more extreme view is that there is no such thing as mental illness in any culture, and that there could not be, because the very notion of mental illness is based on a fundamental mistake or set of mistakes. This sort of view is most closely associated with the psychiatrist Thomas Szasz. It is this view that we will focus on here.

There are many arguments in the voluminous work of Szasz, and it is not easy to always keep them separated. One critic of Szasz separates out at least six main arguments against the existence of mental illness within his work. (Reznek, 1991, Chapter 5).

Sometimes he has compared psychiatry to alchemy or astrology (1974, pp. 1-2), and says they are all pseudo-sciences. On this criticism, it seems that the reason that mental illness does not exist is the same sort of reason that phlogiston or astral influences do not exist: it is an empirical mistake caused by flawed methodology. The continued belief in mental illness by psychiatrists is the result of dogmatism and a pseudoscientific approach using *ad hoc* defenses of their main claims. He also accuses psychiatrists of secrecy and obfuscation.

However, it seems that his most fundamental criticism is not of the scientific methodology of psychiatry, but of its concepts. His claim is that the concept of mental illness is based on a confusion.

> [The belief in mental illness] rests on a serious, albeit simple, error: it rests on mistaking or confusing what is real with what is imitation; literal meaning with metaphorical meaning; medicine with morals. (Ibid, p. x.)

Ssasz says that there cannot be mental illness, literally speaking, because it is no more than a metaphor. He argues that by definition, "disease means bodily disease." (Ibid, p. 74), and further, the mind is not

literally part of the body.

Szasz's critique of the foundations of psychiatry has attracted a great deal of attention from supporters and detractors. It has generated debate over the following issues:

1. Is it true that disease, by definition, must refer to bodily disease?
2. Is it true that the mind is not literally part of the body? Couldn't the mind be identified with the brain or the neural system?
3. Is it true that that medicine is, intrinsically, not about the moral evaluation of behavior, even if it might be used instrumentally as part of a moral evaluation?
4. Is it true that psychiatry is founded on pseudoscience?

Szasz's position has not gained any widespread credence. Given the progress of neuroscience and our increasing ability to affect emotions, thought, and behavior through medication, psychiatry has if anything gained in scientific credibility in the thirty years since Szasz first proposed his critique.

Few of Szasz's supporters have been willing to take as extreme position as him. Critics of psychiatry have been more focused on particular purported mental illnesses, such as alcoholism, psychopathy, multiple personality disorder, rather than the whole category of mental illness. There is still vigorous debate over the reality of such mental disorders. This debate has turned more on empirical issues than the more philosophical claims of Szasz.

2. Is There an Objective Way to Classify Mental Illnesses?

While Szasz's approach is of more historical importance than of current relevance to philosophy of psychiatry, there is vigorous ongoing debate concerning the way that mental illnesses should be classified. There are two aspects to this: what conditions get classified as mental illneses rather than normal conditions, and, among those conditions we agree are mental illnesses, how they are grouped together into different kinds. Controversial diagnostic categories have included homosexuality, psychopathy and personality disorders, attention deficit hyperactivity disorder, and dysthymia. The unitary nature of schizophrenia has come under special scrutiny, as has the unitary nature of autism. This debate spans both empirical and philosophical issues, and it is the former aspect, and the distinction between normality and psychopathology, that has gained the most philosophical scrutiny. The primary questions of concern are:

1. Will it be possible in the future to classify mental illnesses according to their causes, as we do in much of the rest of medicine?
2. Given that we currently classify most mental illnesses according to their symptoms rather than their causes, is there any reason to think that our current diagnostic categories (e.g., schizophrenia, depresssion, manic depression, anxiety disorders) correspond with natural kinds?

3. Is it possible for our current classification scheme in psychiatry to be in any important sense "atheoretical" and independent of any particular theories of the etiology of mental disorders?
4. Is it possible for any classification scheme of mental illnesses to be purely scientific, and is it possible for a classification scheme to be independent of values -- or to ask the reverse, do our classification schemes in psychiatry always rest on some non-scientific conception of what should count as a normal life?

This last question can be extended to all illnesses, and not just psychiatric classification. It is in psychiatry, though, that there is most reason to worry that values enter into the classification scheme, and that there is concern that the profession might be medicalizing what should be seen as normal conditions.

Before we discuss the main approaches here, we should note a couple of points. First, the concepts of disease, illness, abnormality, malady, disorder and malfunction are closely related, but they are not the same. Much careful work has been done trying to find if one of these is more basic than any of the others, or if some of these concepts can be completely analyzed in terms of the others. For our purposes here, we shall gloss over the differences between these concepts. For the most part, we will simply refer to the concept of illness.

Second, even if we could find an uncontroversial general criterion of illness, we would still need to do some work to find a criterion of mental illness. This might seem a simple task, since mental illnesses would simply be those that are illnesses of the mind. But often neurological disorders such as Alzheimer's are not classified with mental illnesses, and there is even resistance from some to classifying them in wider categories such as mental disorder. That seems to be due to the belief that neurological disorders are physical disorders resulting from identifiable damage to the neural system. As we become increasingly able to identify the brain dysfunctions associated with mental disorders, it may well be that the distinction between neurological disorders and mental illnesses starts to fade, as might the professional distinction between neurologists and psychiatrists. It may turn out that a defense of psychiatry does not need to find a clear conceptual distinction between the mental and the physical. Certainly, so far the main debate about finding a criterion of illness has not paid much attention to the problem of finding a criterion of "mental".

A main approach to psychiatric classification is the "medical model". This holds that psychiatric classification is capable of being both scientific and objective. The best-known defender of such an approach is Christopher Boorse, in a series of influential papers. At the other end of the spectrum are theories that psychiatric classification depends solely on the whim or values of those doing the classification, that there is nothing objective about it at all, and that there are no facts about what is normal. These subjective theories are generally proposed in a spirit of criticizing or undermining psychiatry, and are often very sympathetic to the Szaszian view that there is really no such thing as mental illness, and so there could not be a legitimate objective classification of different kinds of mental illness. Often the suggestion that goes with these views is that classification schemes are created to suit the needs of those in power. This view has not often been argued for explicitly, but is at least implicit in the work of Szasz, and it may be implicitly in the work of sociological theorists Peter Sedwick and Thomas Scheff. (See Reznek, 1991, Chapters 6 and 7). Some have suggested that this view underlies the

historical analysis of Michel Foucault. As for its plausibility, the view that the classification is totally subjective or arbitrary stands or falls with antirealism about mental illness, and it has not received much support in the last twenty years.

A middle range of views, sometimes called "mixed" (e.g., Wakefield 1992) hold that diagnostic categories do match real mental illnesses and that there are facts about the world that determine what should be labeled as a mental disorder, but that at the same time, there is an irreducible element of value or normativity in deciding psychiatric categories.

Most debate on classification has been between different versions of mixed models, and with some debate between mixed models and of the medical model. The medical model says that whether a particular condition is normal or abnormal is simply for science to say. It does not pretend that science has provided all the answers and it may concede that there is a great deal more research to be done. It might even concede that we will never be able to collect enough evidence to discover whether a particular condition is abnormal or not: it would conclude in such a case that we cannot know the truth.

It would be highly implausible for a defender of the medical model to insist that values never in fact enter into the psychiatric taxonomy -- a brief study of the history of various categories show that empirical research and neutral scientific facts are certainly not the only things that have been taken into consideration in classification schemes. The medical model claims (a) that it is possible to have a value-neutral classification scheme and (b) it is best to use a value-neutral classification scheme.

In justifying part (b) of their claim, some defenders of the medical model might claim we can discover a *conceptual truth* of the form:

> a disease/illness/malady/disorder/malfunction is a condition that ...

where the ellipsis is filled by some clause such as "reduces the lifespan of the organism," "reduces the productivity of the organism," or "reduces the ability of the genes of the organism to reproduce themselves." However, such an approach is highly problematic because it is very difficult to establish non-trivial conceptual truths about controversial concepts, and it seems clear that our actual usage for the last few centuries of words like disease, illness, or malady do no correspond well with such purported definitions. They are either too broad, too narrow, or both.

An alternative approach to defending (b) is to argue that medicine, and psychiatry especially, should be value-neutral and so its classification scheme should be value-neutral. Note, of course, that there are obvious ways in which we want medicine to not be neutral: for example, it should not be neutral about saving lives or improving health. So we need to be careful about the way in which we want medicine to be neutral. The most appealing interpretation of the idea that medicine, and psychiatry, should be value-neutral is that it should rise above political fighting, and that it should not be influenced by prejudice. However, it is an open question whether being value-neutral and being unbiased are the same. When it comes to deciding what conditions should count as illness, one could be unbiased but nevertheless adopt

a view laden with normative assumptions, or so at least many would argue.

The best way to explain the idea that taking a value-laden stance is not necessarily to be biased is to examine the criticisms of claim (a) above, from theorists who argue that psychiatry and the rest of medicine are inevitably normative. Most such theorists do not infer from this that medicine is always biased; instead, their view is that the nature of psychiatric classification requires that some assumptions are made about what counts as health and what counts as illness, and that these assumptions are not purely scientific. They generally go on to suggest that since medicine and psychiatry in particular have to make such assumptions, it should be as open and honest about it as possible, so that debates about certain categories of psychopathology are not based on a misunderstanding of the kind of enterprise involved. Often they suggest that in a democracy, there should be public debate about what values should be at the heart of medicine and psychiatry.

Those who argue that classification is necessarily value-laden rarely rest their argument on the claim that all science is value-laden, or even more controversially, that all science is subjective. For the sake of argument, it is possible for all sides of the debate to concede that we can know facts about the causes and consequences of the conditions we label as illnesses, and that these facts are entirely value-neutral. (There are of course some who would dispute the possibility of there being, or our knowing, any value-neutral facts, but this is an extreme view, and it does not single out medical classification as an interesting and unusual case of value-ladenness. So we will set it aside.)

We now can ask why those who think that psychiatric classification must be value-laden think so, and how those who think it can be value-neutral propose to find such a classification.

If a theory can, by itself, provide us with a way of demarcating human health from pathology, then the theory must, on its own, have some account of what healthy function is, and what should count as a malfunction of a human being. Those who believe in value-neutral classification generally argue that "health" can be defined scientifically, and thus without value-laden assumptions. Those who disagree think that the criteria used to define "health" are always value-laden, even if they are also based in scientific understanding.

Thus Boorse, who argues for the value-neutral view of classification, suggests that evolutionary theory can tell us what conditions are healthy. In one paper, he gives the following definition of health:

> An organism is *healthy* at any moment in proportion as it is not diseased; and a *disease* is a type of internal state of the organism which:
>
> - interferes with the performance of some natural function -- i.e., some species-typical contribution to survival and reproduction -- characteristic of the organism's age; and
> - is not simply in the nature of the species, i.e. is either atypical of the species or, if

typical, mainly due to environmental causes. (Boorse, 1976, page 62.)

This purported definition has received a great deal of critical discussion. Without setting out all the details of that discussion, we can at least explain the opposing view. There are several possible points to make; here are three:

(C1) In much of medicine, and especially psychiatry, we do not know with any certainty what is evolutionarily natural, because our scientific studies are still in their early stages, and it can be very difficult to find data that will settle scientific controversies. The most promising scientific theory is evolutionary psychology, but this is extremely programmatic. For many conditions, such as homosexual behavior or mild depression, it is not clear whether these conditions help or hinder the continuance of the species (or the continuance of whatever set of genes the theory says is fundamental). Therefore the idea of settling the debates of what should count as illnesses with science is at best a proposal for a distant future time. It is likely that many of the scientific questions will never receive satisfactory answers, in which case we will never be able to use science completely to determine our answers.

(C2) More fundamentally, even were we to have a complete theory of evolutionary psychology, it would still be controversial whether to use such a theory in determining whether particular conditions are normal or abnormal. That is to say, many dispute whether medicine should base its view of naturalness on conditions that help the promotion of the species. For instance, many would claim that medicine is far more individualistic these days, and that we are more concerned with what hinders a particular individual, whether or not it helps the rest of the species, or would have helped the species in times when we were developing evolutionarily. There are two points here: first, that evolutionary psychology does not provide the only possible model of health and illness, and second, that given a choice between two or more models, we have to employ values in making that choice. Thus, even if we adopt evolutionary psychology as the theory to determine what is health and what is illness, this choice is not one based on purely objective scientific criteria, but rather is normatively loaded. For example, Boorse’s evolutionary approach uses illness to mean an internal condition that interferes with a natural function that promotes the continuation of the species, but in deciding between this and an alternative approach, we have to ask whether this model of illness is the best one for us. No value-neutral scientific experiment or theory can answer that question, and we have to bring values into our considerations.

(C3) What’s more, the answers that evolutionary psychology seems to suggest on controversial cases often don’t match with our contemporary practice, and there is serious doubt that a model of health provided by evolutionary psychology is really the one that we should adopt.

Mixed models

Even if the medical model of illness is wrong, it may only require a small modification in order to become acceptable. This is what has been argued by Jerome Wakefield in a number of influential publications. Wakefield attempts to keep the concept of a natural function, and the concept of dysfunction, central in our understanding of mental disorder. Further, he proposes that evolutionary

psychology can explicate which conditions are functional and which are dysfunctional. He suggests that dysfunction is a purely factual scientific concept. So some conditions, even though they may be judged negatively, will not count as disorders because they are not dysfunctions, and are not caused by dysfunctions. For example, some have claimed that children who masturbate have "childhood masturbation disorder." Wakefield says that there is no such disorder, and whatever one's values, such behavior could never count as a disorder because it is not unnatural according to the scientific theory of evolutionary psychology.

However, he concedes that some values must enter in to our decision of what conditions are mental disorders: he argues that some dysfunctions are not judged negatively, and so do not need to be classified as disorders. For example, even if evolutionary theory could show that homosexuality was unnatural, we might not classify homosexuality as a disorder because we might decide that it is not harmful. Our society may have changed so much since the times when our natures were formed that even if a person lacks certain abilities, for example, to be a hunter, and was evolutionarily speaking unnatural, we could agree that the ability to be a hunter is no longer necessary in our society, and so lacking hunter abilities does not mean one has a disorder. Further, some deficits may make us less than perfect, but still we would not judge that we are so lacking as to have a disorder.

This leads Wakefield to the following analysis of a disorder:

> A condition is a disorder if and only if (a) the condition causes some harm or deprivation of benefit to the person as judged by the standards of the person's culture (the value criterion), and (b) the condition results from the inability of some internal mechanism to perform its natural function, wherein a natural function is an effect that is part of the evolutionary explanation of the existence and structure of the mechanism (the explanatory criterion). (Wakefield, 1992, in Edwards, 1997, pp. 87-8)

This analysis is still subject to criticisms C1 and C2 that we set out above. It is less clear that C3 applies to it, since Wakefield's allowing considerations of value to enter in helps the model to better match our intuitions and existing practice.

A different mixed model comes from Culver and Gert (1982, p. 81). This too has been influential.

> A person has a malady if and only if he has a condition, other than his rational beliefs and desires, such that he is suffering, or at increased risk of suffering, an evil (death, pain, disability, loss of freedom or opportunity, or loss of pleasure) in the absence of a distinct sustaining cause.

This model includes a role for objective fact both in the chance of death, pain, etc., and also in determining whether a condition that is caused by a distinct sustaining cause. For example, it would seem that being homosexual can often cause a person to be unhappy, but in at least many and probably most instances, the reason for this is societal prejudice against homosexuals, which would count as a distinct

sustaining cause. So this model would not necessarily entail that homosexuality is a malady, even if the condition makes people unhappy. On the other hand, the model makes it inevitable that values also enter into the determination of what counts as a malady, most obviously in the decision of which beliefs and desires are rational, and which are irrational.

Furthermore, while in a great many cases, it may simply be an empirical issue whether a person is suffering a disability, loss of opportunity or loss of pleasure, there are at least some cases where values can enter into determining what counts as disability, etc. This is clearest in cases where pragmatic considerations (for example, whether a managed care company should provide funding for treatment) require that a definite decision be made about whether a condition is a malady or not, but where it is debatable whether the condition really is a disability or a significant loss of opportunity. Recent debates over the use of medication for erectile dysfunction have vividly illustrated this for physical disorders; if a man has a condition that means that he is only able to have sex twice a week without taking medication, does that mean he has a disability? It is hard to see how one could provide an answer to this question without making assumptions about what is normal. Also, in recent years some advocates for the deaf have argued that deafness is not a disability, but is rather simply a difference from people who can hear; this too suggests that values can enter into our understanding of what counts as disability. In the realm of mental health, it can be argued that whether a person has lost freedom, for example in the controversial category of substance dependence, different observers may agree on the empirical facts concerning a person who takes drugs, but may still disagree whether she has a disability, and even whether she has diminished freedom; the difference can depend on what normative assumptions are made. For a different example, we can consider a case where a person who in her teen years experienced productive and pleasurable hypomanic episodes, but who by her twenties no longer has such episodes, has undergone a change that should count as a disability or a loss of opportunity. The approach of Culver and Gert does not rely on evolutionary psychology, and so avoids the problems set out in (C1) and (C2) above. If the preceding argument is correct, however, and the criteria for what count as an evil can depend on normative assumptions, then Culver and Gert's general definition of malady suffers from a problem of circularity.

Multiple Personality

There have been many other proposals for how to provide criteria of mental illness. We do not have the space to discuss them all in this section. Furthermore, there have been many contested mental disorders, such as schizophrenia, autism, addiction, homosexuality, attention deficit hyperactivity disorder, oppositional defiant disorder, antisocial personality disorder, and dysthymia. We do not have space to discuss them all, and indeed, the attention these conditions have received has rarely been from philosophers but from other psychiatric critics with different backgrounds.

We will discuss one condition that has gained philosophical scrutiny, that of multiple personality. Philosophers have been particularly interested in this phenomenon because it raises important issues of the understanding of the unity of consciousness and it may be an important test case for various theories of personal identity, maybe providing a counterexample to any theory that implies that there can no more

than one person "in" one body. But in order to discuss these aspects of the phenomenon, philosophers have had to first address what the phenomenon really is. In particular, various skeptics have argued that there is no such thing as multiple personality, or that it is in some way artificial or inauthentic.

In order to introduce the interesting philosophical work on the reality of multiple personality, it is necessary to give a very brief sketch of what it is taken to be.

In multiple personality, it seems that there are at least two distinct personalities within one person. These personalities, or "alters," apparently have profoundly different voices, speech patterns, self-descriptions, memories, character traits, beliefs, desires, and levels of education. Different alters within one body can describe themselves as being of different ages, genders, ethnicities, skin color, height, weight, and eye color. Different alters within one body can fail to be aware of each other, but there can be interaction between them. Sometimes awareness is one-directional: A is aware of the thoughts and actions of B without B being aware of A. Sometimes one alter can directly interfere with the thoughts or actions of another alter. Or so they claim. The number of people diagnosed with multiple personality has varied greatly over time and place: it was first described in the nineteenth century, especially in France and the USA; and after it seemed to become almost non-existent in the first half of the twentieth century, it grew again in the second half, especially in the USA.

There has been a great deal of empirical and methodological debate about the causes and the treatment of multiple personality. It seems that it is linked with childhood abuse, and it may be that splitting into two, or dissociating, is a way of coping with a traumatic experience while it is happening or after it is over. It is also linked with another controversial phenomenon, hypnotism. People who are highly hypnotizable seem to be especially prone to becoming multiple personalities. Sometimes hypnotism has been used by therapists as a way to discover "hidden" personalities.

Skeptics have raised different sorts of objections to multiple personality. Their objections are of several different kinds; here are three.

> (S1) Some have claimed that multiple personality does not exist at all, and it is a hoax by patients and therapists seeking attention or money, or hoping to use it as an excuse for criminal behavior.
>
> (S2) Some have claimed that multiple personality is not really a separate phenomenon, but rather is a unusual form of other mental disorders, such as manic depression, schizophrenia, or borderline personality disorder. This raises a taxonomic issue of when a condition should be classified as an atypical form of a known mental disorder rather than as an instance of a separate, independent mental disorder.
>
> (S3) Some have claimed that multiple personality, while a separate disorder, is caused not by traumatic childhood experiences but rather by overenthusiastic and irresponsible therapists. Vulnerable patients have been encouraged to believe that they have been abused

> as children. The treatment they have then received from therapists, especially hypnotism, has not discovered, but rather created separate personalities.

All of this so far is mostly an empirical matter, depending on a careful scrutiny of the existing data, careful thought about our present taxonomic categories, and probably pointing to further possible research. By far the most sophisticated philosophical work on the reality of multiple personality has been by Ian Hacking, in a series of papers and books since the mid 1980s. Hacking combines careful historical research, an understanding of statistical methods and scientific research, and a grasp of philosophical debates about realism, truth, and nominalism. He addresses the approach of the social sciences, and in particular the claim that psychiatric phenomena are socially constructed. This seems to amount to the claim that while in some sense there might always have been multiple personalities, it is a socially constructed phenomenon in the sense that we have started to bring certain concepts and patterns of ideas to bear on the phenomenon, and that a number of political and social factors are what has led us to frame our thought in this way. This view denies that a label such as multiple personality picks out a natural kind of people.

Hacking does not seem sympathetic to skeptics of the variety (S1) and (S2). In some of his work he seems quite sympathetic to (S3) and also to some of the insights of social constructionism. But he goes beyond most simple forms of social constructionism, and introduces the idea that the people classified by social categories will themselves be affected by the classification. So the issue is more than simply a matter of discussing what concepts we use in framing psychopathology.

> People of these kinds can become aware that they are classified as such. They can make tacit or even explicit choices, adapt or adopt ways of living so as to fit or get away from the classification applied to them. These very choices, adaptations, or adoptions have consequences for the group, for the kind of people that is invoked. The result may be particularly strong interactions. What was known about people of a kind may become false because people of that kind have changed in virtue of what they believe about themselves. I have called this phenomenon *the looping effects of human kinds*. (Hacking, 1999, p. 34).

Hacking has suggested that once we understand these interactions between our categories and the people categorized, we should stop wanting a simple yes or no answer to the question "is multiple personality real?" He argues that there has been a great deal of confusion in debate between the sides often labeled as constructionists and realists, not just about multiple personality, but a whole range of phenomena and categories, including subatomic particles, childhood, emotions, and women refugees. He argues that a central assumption for anyone who argues that X is socially constructed is

> [0] In the present state of affairs, X is taken for granted; X appears to be inevitable.

Those who argue for some forms of social construction of X argue that it is not in fact inevitable, and could be different. Some are content to be purely descriptive about this, while others, taking a stronger position against X, argue that we should construct our categories differently and do away with X, or at

least view the category of X with some suspicion and recognize its contingency.

Even though Hacking finds the language of "social construction" mostly unhelpful, he views dissociation and multiple personality with some suspicion. He calls it an example of an *interactive kind*, created by looping effects, and he explicitly hopes that the category dies away (Hacking 1998, p. 100). He further argues that it is problematic to use cases of multiple personality and dissociation to draw conclusions about the fundamental nature of the mind or personal identity. "Multiple personality teaches nothing about 'the self' except that it is an idea that can be exploited for many ends." (Ibid, p. 96).

Hacking has provided us with the most detailed and careful philosophical approach to addressing issues in classification of mental disorders. His work is bound to be influential.

3. When are People with Mental Illnesses Responsible for Symptomatic Behavior?

There are philosophical positions that say that people are never responsible for their behavior, because their behavior is always determined. There are also some philosophers, such as the early Sartre, who have made statements that seem to imply that people are always responsible for their behavior, or at least all their intentional actions. (See the entry on freewill.) These are, however, extreme positions, and a far more widespread view is that of common sense: people are normally responsible for their behavior, but there are sometimes circumstances that provide them with an excuse. There is still considerable debate as to what makes a good excuse. In past decades some sociological analyses have led to suggestions that some people turn to crime, for instance, because of poverty or discrimination, and that this provides some excuse for the criminal behavior. In more recent decades, such views have received less support. However, there is still considerable support for the idea that people with mental illnesses are not fully responsible for those actions symptomatic of their illness. To what extent people are responsible, and which mental illnesses provide excuses, are issues still very much up for debate.

Three mental illnesses that have received attention from philosophers and psychiatric theorists on the issue of responsibility are schizophrenia, psychopathy, and alcoholism. There are of course many other mental illnesses where the issue of responsibility arises: obvious examples are depression, obsessive-compulsive disorder, manic episodes, paraphilias, and borderline personality disorder. Despite the fact that the various theories of the etiology and nature of these disorders are very suggestive of ways to understand the responsibility of those with the disorders for their symptomatic behavior, these and other mental disorders have received surprisingly little discussion from philosophers vis-à-vis responsibility for action. So we will focus on the disorders that have been discussed.

Schizophrenia

One of the most typical symptoms of schizophrenia is the suffering of delusions. When people with

schizophrenia are suffering extreme and pervasive delusions, they do not understand what they are doing. It is no simple matter to define a delusion, and it is highly problematic to simply equate it with a false belief, but it is safe to say that paradigm cases of delusion imply a significant lack of, or distortion in, understanding of one's situation. In paranoid schizophrenia, for example, patients tend to interpret what other people say with what might be called a hermeneutics of fear and suspicion, and in extreme cases, will have elaborate and fixed fantastic theories about ways in which others are aiming to harm them.

It should be emphasized that schizophrenia causes far more than cognitive distortions. It is a disorder that causes great emotional problems as well, and these often contribute to the bizarre behavior of schizophrenics. Nevertheless, it is the distortions in belief and reasoning that provide the clearest excuse and make it plausible that often schizophrenics are not responsible for their behavior.

It is this sort of case that is central to the insanity defense in the law, and which has received considerable discussion by philosophers and psychiatrists interested in the justification of punishment. There are many different kinds of cases where mentally ill people seem to have some grasp of what they are doing, and that what they are doing is wrong, and it is very difficult to draw clear lines between somewhat similar cases.

Psychopathy

The category of psychopathy is one of the more controversial within psychiatry. The closest that the diagnostic manual DSM-IV-TR comes to this diagnosis is antisocial personality disorder, and the whole category of personality disorder has come under critical scrutiny. Antisocial personality disorder, and the corresponding diagnoses for youth, (behavioral disorders and oppositional defiant disorder), have been especially questioned because they include as symptoms destructive and often criminal behavior. There is a great deal of suspicion of any attempt to excuse the symptomatic behavior of psychopaths.

Some of the debate hangs on the correct explanation of the behavior of psychopaths. Psychopaths are often intelligent and calculating, yet they are also impulsive and pay as little regard for their own long-term interests as they do for that of other people. They can be very emotional, yet they also seem to lack some emotional capacities. In particular, it is still an open question to what extent they comprehend the wrongness of their actions, and can be said to have a conscience. If their moral understanding is extremely limited -- for example an ability to list the kinds of actions that would be classed as morally wrong, but no ability to empathize with those who suffer -- then there is still philosophical work to be done in deciding what this implies for moral responsibility, punishment or treatment.

Another characterization of psychopaths is that they are simply people with deeply flawed characters and no use for morality. This characterization is probably closer to media portrayals of psychopaths than clinical reality, but it still raises philosophical issues. In particular, we can ask, if a person has a bad character, and lacks any interest in or feeling for the welfare of others, then he may not be able to behave well. How can we blame someone for doing what is in his nature? This is an issue for moral theory generally, and arises especially for virtue theory. It is of particular practical consequence when it comes

to judging psychopaths, if this account of their behavior matches any real psychopaths.

To go further into the philosophical discussion of psychopathy would require setting out empirical discussion and ethical theory in far more detail, so we will leave this discussion of psychopathy.

Alcoholism

There has been a great deal of discussion of whether alcoholism should count as a disease, by physicians, philosophers, legal theorists and policy makers. Many factors enter into the discussion, but one way of understanding the literature is that it centers on the issue of whether alcoholics are responsible for their continued drinking. It is plausible that alcoholism is a disease if and only if alcoholics are in some significant way (in need of clarification) not responsible for their drinking. What is less clear is which is logically prior, the disease status of alcoholism or the responsibility of alcoholics for their drinking.

Often one finds claims in popular discourse to the effect that alcoholics are not responsible for their drinking because the drinking is a symptom of a disease, or because it is the disease that causes them to drink. If this is the case, there must be independent evidence that alcoholism is a disease: various sorts of evidence have been suggested, including the withdrawal symptoms that alcoholics experience when they abstain from drinking, physical changes that occur in the brain as a result of excessive long-term drinking, and epidemiological studies that show that there is a genetic component to alcoholism.

It takes little thought to see, however, that these sorts of evidence can't by themselves prove that alcoholism is a disease. How one proves that a condition is a disease depends partly on what criteria of disease we can agree upon, but even without giving a definition of disease, one can see that the claim that the empirical evidence entails that alcoholism is a disease is highly contestable. The existence of withdrawal symptoms does show that it is difficult to stop drinking, but there is a great logical distance between having a habit that is hard to give up and having a disease. The fact that brain abnormalities occur in excessive drinkers is suggestive of a physical disorder, but abnormalities in themselves do not constitute diseases or disorders. The fact that heavy drinking causes changes in people's brains is not in itself surprising. Further evidence about what the effect of the brain abnormality has on the person would be needed, and its correlation with heavy drinking is not enough. Finally, the fact that a habit such as heavy drinking has a genetic component again does not prove that it is a disease. Laziness and cowardice could also turn out to have genetic components, but that would not make them diseases.

The problem for the disease status of alcoholism is that a habitual drinker can be described with such strongly evaluative terms as weak, self-deceiving, selfish, self-destructive, shortsighted, uncaring about other people, and even pathetic. Some would claim that such psychological characteristics provide the best explanation of an alcoholic's problem drinking, and if this is right, then the alcoholism-as-disease explanation is at best secondary, and at worst, utterly wrong-headed. While it is hard to find a description of self-destructive heavy drinking that makes it simply a matter of personal decision, an expression of one's values, or a rational choice, it does seems that problem drinking can often be a self-perpetuating way of life. It is difficult or impossible to locate a specific single cause of the drinking, and it also seems

that the drinker has a role in perpetuating her problem. It is not simply something that happens to her.

Nevertheless, the testimonials and behavior of alcoholics also provide grounds for thinking that they have extreme difficulty in giving up drink, and often no simple exertion of willpower or resolution to give up will solve the problem. Often heavy drinkers try to stop or cut back but fail to do so, even when they know full well that terrible consequences will result from their continuing to drink, and when drinking does not provide pleasure or lasting benefit.

This sort of argument suggests that it is in fact the issue of personal responsibility that is logically prior, and the question of whether alcoholism is a disease depends on it. Thus, the argument would go, alcoholism is a disease because alcoholics cannot control their drinking.

Now, it is very plausible that self-control is a matter of degree; people have more or less control over their behavior. Some people are better at resisting temptation than others. It is rare for a person to have complete control over her actions, and it is almost unimaginable for a person to have no control whatsoever over her actions. It would seem to follow that there must be some degree to which alcoholism is a disease, or to put it another way, the disease status of alcoholism is not all-or-nothing.

However, at least for the purposes of public policy in present circumstances, there is no room for a concept of a condition that is a part or semi-disease. It tends to be that policy must come down on one side or the other on the question whether alcoholism is a disease, but that given the nature of alcoholism, the issue is not simply settled by the scientific and psychological facts. It follows that other considerations can come into play, such as considerations about the social and economic effects of labeling alcoholism a disease. These considerations may tip the scales one way or the other. This may provide a justification of current practice where alcoholism counts as a disease for some purposes but not others. For example, under US law, alcoholism is not a disability covered by the Americans with Disabilities Act, and so is not a condition employers must make allowances for. But treatment of alcoholism by federal health care organizations (such as the Veterans Administration) is mandated by law.

Philosophers have started to discuss the irrationality of alcoholics, how to explain their symptomatic behavior, and to what extent they are responsible for their behavior. Notable examples are Gary Watson (1999), Alfred Mele (1996), and Jon Elster (1999a). There is an astonishing amount of empirical research and psychological models aiming to explain alcoholism, and philosophers will probably find, as they have found with much work on emotion and social psychology, that the literature contains questionable assumptions about fundamental psychological concepts. Central to the philosophical discussion is the examination of the possibility of irresistible desires and the way that cravings can reduce an addict's self-control. Indeed, addiction can provide an important test case for any theory of the nature of action, since it is a prime example of irrationality, and it is important that theories about the nature of practical reasoning be able to give an adequate account of the nature of irrationality.

There is some overlap between this topic and that of the responsibility of weak willed agents, although so

far there has been little systematic discussion by philosophers of the relation between addiction and weak willed action.

Economic Analysis of the Law

Economic analysis of law applies the tools of microeconomic theory to the analysis of legal rules and institutions. Ronald Coase [1961] and Guido Calabresi [1961] are generally identified as the seminal articles but Commons [1924] and Hale [1952] among others had brought economic thinking to the study of law in the 1910s and 1920s. Moreover, as I will elaborate below, economic analysis of law derives from several different intellectual traditions in economics.

Richard Posner [1973] brought economic analysis of law to the attention of the general legal academy; by the late 1970s, his work had provoked a vigorous controversy within the legal academy. That controversy has usually defined the debate around the philosophical foundations of economic analysis of law. Posner made two claims: (I) Common law legal rules are, in fact, efficient; and (II) Legal rules ought to be efficient. In both claims, "efficient" means maximization of the social willingness-to-pay. In the course of the controversy, two other claims were articulated in Kornhauser [1984, 1985]: (III) Legal processes select for efficient rules; and (IV) individuals respond to legal rules economically. (In this third claim, "efficient" means "Pareto efficient.") Kornhauser identified this last, *behavioral* claim as central to the enterprise. A fifth claim is also implicit in the literature: (V) on the best interpretation of law, common law doctrines promote efficiency.[1] Notice that (V) differs from (I) in important respects. According to (V), an economic interpretation fits a doctrine not because, as asserted in (I), the legal rules in fact induce efficient behavior but because the rule would induce efficient behavior within the view of the world that seems to underlie the judicial decisions. (I) is an empirical claim that requires the analyst to determine whether the actual behavior induced by legal rules is efficient; it requires knowledge of how individuals do, in fact, behave and of which behavior in the real world would, in fact, be efficient (V) requires only knowledge of the content of judicial opinions; the analyst interprets these opinions to extract an economic model that underlies the decision. (V) might be true even though legal rules induced inefficient behavior in the real world because the announced legal rule might be efficient within the implicit model used by judges.

These five claims do not correspond directly to traditional questions in the philosophy of law. The *evaluative claim* (II) that legal rules ought to be efficient would, if directed to judges, qualify as a theory of adjudication, one of the central concerns of anglo-american philosophy of law. Central philosophic questions concerning the concept of law, of its normativity, and the obligation to obey the law, however, are not directly addressed. The behavioral claim as well as the evolutionary claim (III) and the positive claim (II), by contrast, concern empirical issues that philosophers of law generally neglect. Nevertheless, the controversy within the legal academy has generally regarded economic analysis of law as providing a comprehensive theory of law that challenges traditional approaches to law. Indeed, an explanation of the

vehemence of the controversy should identify differences in fundamental views concerning law.

---

1. Two Strands of Thought within Economic Analysis of Law

The vast literature of economic analysis of law is not easily characterized. For purposes of this essay, I identify two distinct strands of thought within economic analysis of law. I shall call one strand *policy analysis* and the second strand *political economy*.[2] These two strands may be differentiated along a number of dimensions.

First, policy analysis generally focuses on analysis of the effects of legal rules and institutions on *outcomes*. An outcome usually consists of the "objective" effects of the rule or institution on the behavior of "private" individuals. By contrast, political economy generally investigates the operation of political institutions such as courts, legislatures, the executive and administrative agencies; it usually focuses on the behavior of the public officials within those institutions. Ideally, one would trace the effects of different institutional rules and structures through the behavior of public officials to the effects on the behavior of private individuals. In practice, however, tracing effects of changes in institutional rules to final outcomes is too difficult and too uncertain. A change in the structure of legislative institutions, for example, would likely affect the content of the legislative programs enacted in the jurisdiction. To trace effects to final outcomes in terms of the behavior of private individuals would thus require the analyst to predict the set of statutes that would be enacted within various legislative structures.

Second, and related to the first, policy analysis generally assumes that public officials in general and judges in particular, are conscientious. Judges thus enforce the legal rules as they are announced, regardless of the judge’s own view of the desirability of the legal rule or its impact on her personally. Political economy, by contrast, assumes that public officials have the same motivation as private individuals; they are self-interested. In the context of adjudication, as will be elaborated below, the political economist interprets self-interested judicial behavior as decisions that promote the policy

preferences of the judge.

Third, policy analysis generally adopts a welfarist stance towards evaluation of legal rules while political economy has evolved from a more contractarian tradition. Policy analysts, when evaluating legal rules ask whether that legal rule induces behavior that satisfies some welfarist criterion, usually either Pareto efficiency or (constrained) social welfare maximization.[3] Political economy, however, has to a large extent emerged from an economic tradition, exemplified by James Buchanan,[4] that rejects the maximization of social welfare as a criterion and seeks to evaluate political institutions on grounds of consent or, more generally, within the contractarian tradition.

Fourth, we might understand the distinction between policy analysis and political economy as a difference in the view of the instrumentalism of law. Policy analysis tends to proceed legal rule by legal rule. It asks, for example, how does a change in the standard of care affect the behavior of tortfeasors and tort victims? Or how does contracting behavior differ if the measure of damages shifts from expectation damages to reliance damages? The analyst thus imputes a purpose (usually, but not necessarily, of maximization of social welfare) to the promulgator of the legal rule. The analyst then assumes that the policymaker has chosen the legal rule that best promotes her (imputed) objective. Legal rules are then instrumental to the achievement of the posited goal; call this approach *rule instrumentalism*.

The political economist, by contrast, generally denies that any purpose can be attributed to the promulgator of a legal rule largely because legal rules are not promulgated by a single individual with power to control unilaterally the content of the rule. Certainly, from the perspective of political economy, legislators have no common purpose and one should not assume or expect that any statute maximizes social welfare. Legislation results from the interplay of interest groups that do not reflect all interests within society. Even if the legislature did reflect all interests within society, each interest does not have an equal (or proportionate) say in the formulation of the statute.[5] Finally, even if each interest did play a "proportionate" role in the formulation of the statute, Arrow's General Possibility Theorem teaches that the aggregation of interests might still not yield a coherent purpose. Political economy thus rejects rule instrumentalism.

One might attribute the rejection of rule instrumentalism within political economy to a commitment to an explanatory rather than a normative project. At the level of constitutional political economy, however, the research program usually adopts the perspective of a constitutional designer and this designer arguably has a view of law that includes *institutional instrumentalism*: i.e., legal institutions, rather than specific legal rules, promote the specific goals of the constitutional designer.[6] The constitutional designer seeks a political structure that promotes her goals. The project of constitutional political economy is thus normative in nature. Indeed the normative nature of the project dominates any explanatory aim. Many within the project - see Brennan and Buchanan [1981, 1985] - argue that one ought to adopt an economic theory of behavior of public officials and private individuals even if that theory is not the best explanatory theory.

These last two differences suggest that the two strands of economic analysis of law may endorse radically

different positive and normative theories of adjudication. These theories are sketched and discussed in section 5 below.

More significantly, for purposes of this entry, however, is the basic similarity between these two strands of economic analysis of law. Both of these strands adopt the standard assumption of neo-classical economics that each individual seeks to maximize her preferences. Moreover, they generally assume that each individual acts in her own self-interest, narrowly defined. This approach presents the single, greatest obstacle to the articulation of a general theory of law that confronts economic analysis: it has no room for the *normative* aspect of law. It is this denial of the normativity of law that accounts for the vehement resistance that economic analysis provoked within the legal academy.

2. The Concept of Law

Though commentators often characterize economic analysis of law as providing a comprehensive theory of law, its narrower ambitions become apparent when one realizes that economic analysis of law has not explicitly addressed the question "What is law?". Indeed, economic analyses of law generally *presuppose* a concept of law in that the law is uncontroversially known to all actors.

One might extract two quite different accounts of the concept of law from the practice of economic analysts. On one interpretation, economic analysis of law relies on a straightforward theory of legal positivism. On the second interpretation, at which the end of the last section hinted, economic analysis of law assimilates the analysis of law to the analysis of social phenomena generally; it postulates, then, that there is no analytically useful concept of law.

2.1 Legal Positivism and Policy Analysis in Economic Analysis of Law

The policy analysis strand of economic analysis of law often implicitly adopts some variant of legal positivism as its understanding of the concept of law. Recall that the policy analysis treats the behavior of judges in particular (and sometimes public officials generally) differently from the behavior of those subject to the legal rules.

An economic analysis of the behavioral effects of a legal rule generally begins with the assumption that the legal rule is clearly known not only to judges and other public officials but also to those subject to the legal rule. This knowledge of private citizens might amount simply to the knowledge of what consequences follow from each possible action the agent might take. Actions that provoke a response from public officials generally, or judges in particular, have no special character to them; the citizen in her deliberations treats the consequences of rule-following or rule-breaking as she treats any other price. On Hart's account of legal positivism, however, a private citizen may adopt this detached attitude towards legal rules. The concept of law inherent in policy analysis is thus consistent with positivism.

The typical model, however, assumes that public officials conscientiously apply the legal rule under study. The public official does not identify the rule that would best promote her own preferences and then apply (or not apply) that rule; rather she "conscientiously" applies the rule that "ought" to govern the event. Conscientious application here simply implies that the official may uncontroversially apply an identified legal rule to the events in question.[7] This assumption might reflect a "partial equilibrium" approach to the analysis of the problem at hand. If the effects of the legal rule are the central focus of inquiry, the incentives and behavior of public officials who enforce that rule may be of less interest. The analysis of the institutional structures and processes that insure the "conscientious" application of law by public officials are left for later analysis.

Other aspects of the economic analysis of law are consistent with this positivist approach to the law. Economic analysis of social norms, for example, often provides a characterization of social norms that largely coincides with Hart's own scheme for distinguishing social rules that are legal rules from social rules that are not. Specifically, economic analysts of law point to the decentralized character of the promulgation and enforcement of legal rules as the properties that distinguish social norms from legal rules.

2.2 The Elimination of Distinctively Legal Phenomena

As noted earlier, economic analysis of law has no room in its theory of behavior for normative concepts, including ones as basic to law as duty and rule.[8] This aversion to normative concepts takes a moderate form within the policy strand; private individuals act only prudentially but public officials act conscientiously to meet their legal obligations. The political economy project within economic analysis of law adopts a more extreme ambition; both private citizens and public officials have only prudential motivations. Political economy aspires to eliminate normative motivations; or at least to reduce normative motivations to prudential ones. This ambition has dramatic consequences for one's understanding of law.

2.21 A Legal System as a fusion of a legal order and a legal regime

Legal phenomena present philosophical problems in significant part because they have both normative and institutional aspects. I shall call the normative aspect of a legal system the *legal order* and the institutional aspect the *legal regime*. Together, the legal order and the legal regime constitute the *legal system*. The legal order consists of the legal norms of the system; these norms are expressed in (but not co-extensive with) the Constitution (if any), statutes, administrative regulations, and judicial decisions of the jurisdiction. The legal regime consists of the legal institutions extant in the jurisdiction. These clearly include the legislatures, executives, administrative agencies, and courts but also may include such institutions as the bar and legal education.

One might create a taxonomy of legal theories in terms of the relation between the legal order and legal regime presumed by that theory. It is useful to characterize two extreme positions within this taxonomy. At one extreme, the legal system is understood completely in terms of the legal order. At the other extreme, the legal system is understood completely in terms of the legal regime.

What does it mean to understand the legal system solely in terms of the legal order? More specifically, how does one understand the legal regime solely in terms of the legal order? Hart's legal positivism provides a useful starting point. As Hart notes, the legal order consists of both primary and secondary rules. Secondary rules are constitutive of the legal regime; they define the powers and obligations of public officials. For secondary rules to explain fully the legal regime, they must create a comprehensive set of obligations; that is, the obligations of a public official must dictate her action in every instance. Hart, of course, denied that secondary rules could do this so his positivism does not lie at this extreme end of the taxonomy.

A comprehensive specification of the obligations of public officials is not sufficient to explain the legal regime solely in terms of the legal order. In addition, one must assume that public officials are *conscientious*.[9] A conscientious public official always *meets* her obligations. Moreover, she always meets them for an appropriate reason. Moral reasons are appropriate reasons for meeting an obligation. Prudential reasons are inappropriate in the sense that the secondary rules would then not serve as a motivation for the agent.

The parallel question posed by the other extreme is more easily understood. To understand the legal order solely in terms of the legal regime requires only that one defines norms of the legal order in terms of the behaviors of the public officials within the legal regime. The legal order plays no role in the motivation of public officials. More strongly, one might argue that the legal order does not determine which individuals are public officials. Rather, the behavior of a certain group of individuals determines what obligations other individuals have. Here "obligations" are defined solely in terms of the consequences that follow from non-compliance. That is, individuals have purely prudential obligations.

Notice that Hart's legal positivism might be understood as falling close to either extreme category of this taxonomy. I elaborated the explanation of the legal regime in terms of the legal order by reference to Hart's legal positivism. Consideration of the grounds of acceptance of the rule of recognition permits one to see how Hart's positivism might be understood to explain the legal order solely in terms of the legal regime. The rule of recognition is defined behaviorally in terms of the rule that law-applying public officials accept. The reason for acceptance is controversial. Hart [1961] seems to place no restriction on the motivation a public official might have. Others [e.g Holton, 1998], however, have argued that public officials must have a moral reason, not a prudential one.

2.22 Political economy and the concept of law

Political economy aims to explain all legal phenomena in terms of the self-interest of agents; it renounces the concept of normatively guided behavior. For the political economist, then, the legal regime explains completely the legal order because it interprets legal obligation solely in terms of the incentives that "legal rules" create for individuals.

On this account, of course, legal rules do not play any role in the explanation of behavior of either private individuals or public officials. An individual faced with a choice considers the costs and benefits that each

option presents to her. These costs and benefits will include "legal costs and benefits" but these costs and benefits are not determined by rules; they are the result of the incentives that private and public officials face. Rules are only rules of thumb that express the response of average individuals under normal circumstances to particular events. Which rules of thumb are used, of course, may greatly affect the social equilibrium achieved in a particular jurisdiction.

3. The Obligation to Obey the Law

In the previous section, I discussed the role that legal rules played in the practical deliberations of private agents. On that account, the sanctions imposed for non-compliance with the rule provided agents with prudential reasons to conform the legal rule. Independent of those sanctions, however, the agent had no reason to obey the law. I argued further that, within the political economy strand of economic analysis of law, public officials had only prudential reasons for conformity to their public obligations. From the perspective of the last section, then, no one has a general obligation to obey the law.

In this section, I suggest that economic analysis nonetheless offers a structure within which one may articulate prudential accounts for a general obligation to obey the law.

3.1 Equilibrium Selection

Legal positivism grounds law in social practice. Its difficulty in explaining the normativity of law emerges directly from this attention to the social nature of law; social facts themselves, it would seem, cannot give rise to any obligation. Various authors (e.g., Postema [1982]) have tried to resolve this conundrum through an analysis of convention as a coordination game.

In a coordination game, the interests of all players are coincident; each player ranks the possible outcomes of the game identically. The difficulty for the players arises because they do not know which of the multiple equilibria of the game to play. Consider, for example, an island in a pristine legal state-there are no legal rules. The individuals must decide on which side of the road to drive. Formulated as a game, each individual has two strategies: drive on the right (*R*) and drive on the left (*L*). Each has an identical evaluation of the outcomes of the strategy choices of everyone. Each ranks the outcomes in which everyone chooses the same side of the road -- all *R* or all *L* -- highest and each ranks the outcome in which half choose *R* and half choose *L* worst.[10] This game has two equilibria: all choose R and all choose L. Unfortunately, knowledge that two equilibria exist does not help agents determine which strategy to adopt, or, alternatively which equilibrium to play.

Announcement of a legal rule in this context can coordinate the players' actions. It gives each a reason to choose as the rule dictates if it affects the individual's beliefs concerning which strategy the other agents will adopt. On this account, the social fact that individuals accept the law provides each individual with a reason to act. This reason is independent of any sanction that the law might impose for non-compliance. Moreover, this reason is prudential in that it best promotes the agent's own welfare and moral, in the

sense that it best promotes the well-being of all. This coincidence results from the coincidence of interests of all agents.

Law understood as a coordination device at best provides a partial account of the grounds of normativity. Obviously, many if not most laws concern conduct in which the interests of agents do not coincide. Coordination cannot provide agents with a reason to act in this case. Moreover, it is not clear that the acceptance of a rule of recognition by public officials constitutes a coordination game. Consider a specific judge *J*. That judge may think rule R is the best rule of recognition. Consistent with that belief she considers a world in which all judges accept *R* as best. Nothing guarantees that a second judge J′ consider *R* best. He may think R′ better. J′ will also believe that a world in which all judges accept R' is best. But it is not obvious that *J* must consider a world in which all accept R′ as preferable to one in which a majority accept *R*.

Finally, note that the argument is incomplete. It requires that individuals have sufficiently common knowledge of the law and that others know the law for it to have any plausibility. Even under these circumstances, however, the argument still requires that each infer from this common knowledge that each individual will comply.

3.2 Bounded Rationality and the Conservation of Decision Resources.

In the simplest model in which such an account exists, agents face a cost to deliberation. The more complex the deliberative calculation, the more costs the agent incurs. When the marginal cost of deliberation is sufficiently high, the agent might do better to follow a rule of thumb that quickly, and cheaply, identifies a good but not optimal, action.[11] If the expected benefit from choosing the optimal action (relative to the good action) is less than the cost, it is prudent for the agent to adopt the rule of thumb. More sophisticated accounts of an economic rationale for rule-following rely on more complex models of bounded rationality.

To complete an economic account of the authority of law requires that one explain why the agent should consider legal rules as the relevant rules to which she should defer. One might argue that those who promulgate legal rules have special expertise that makes it likely that they will enact rules that are better than the rules that the agent herself would formulate. For some legal rules-technical rules concerning health and safety promulgated by administrative agencies-this argument may have merit. After all the decision at issue depends on a mass of technical data that is not easily assimilable or manipulable. For many other legal rules promulgated by legislatures and courts, however, this argument may not apply.

Several other features of this argument merit attention. First, it parallels the argument for authority offered by Joseph Raz.[12] Moreover, as in Raz's argument, authority is specific to legal rules rather than to law in general. An agent might believe the law more expert than she with respect to some decisions than to others. In fact agents with different expertise themselves would find different legal rules authoritative.

Second, on this account of authority, the legal rule affects the agent's deliberation not because of the sanction for non-compliance-as in the view of legal rules as incentives--but because compliance with the legal rule even in the absence of a sanction is in the agent's interest. This feature of the account of authority conforms to notions, developed further below, of the way in which rules enter the deliberative process. But this feature also limits the applicability of the account to those legal rules that bear on the agent's immediate interest. Many legal rules direct the agent to adopt actions that raise her own costs; in the absence of a sanction for non-compliance her own interest would dictate non-compliance. So, for example, a rule requiring that an agent adopt due care in certain activities may raise the agent's costs.[13]

The prudential account of authority outlined above primarily addresses private individuals. One might ask the parallel question concerning the obligation to obey the law of public officials. In some respects, this question has greater significance than the question concerning private individuals because many acknowledge that the motivation of private individuals to obey the law is usually prudential, the desire to avoid sanction. Moreover, on some jurisprudential accounts, most notably H.L.A. Hart's version of legal positivism, the attitudes and behavior of public officials determine the existence and nature of law.

The economic account of authority, however, does not provide a compelling explanation of official behavior. Consider how the economic account applies to public officials. The relevant obligations here are the official obligations of the individual: the judicial obligation to decide cases according to the dictates of *stare decisis* and other obligatory practices; the executive official's obligation to apply the law. Two difficulties arise immediately. How is compliance with these official obligations in the individual's interest? Why must the agent follow a rule rather than optimize in each instance? This second difficulty is less troublesome than the first; Ronald Heiner [1986], for example, has offered a prudential account, grounded in bounded rationality, of the judicial obligation to adhere to *stare decisis*.[14]

One might attempt to resolve the first difficulty concerning the agent's interest by arguing that compliance with official obligation is in the individual's interest because she desires to maintain her employment. But this explanation rests on an incentive argument. The sanction of dismissal induces compliance rather than a normative motivation to comply with one's obligation; it is another prudential account. The prudential account of authority thus fails to overcome this first difficulty. It is not clear then that the prudential account of authority can ground a positivist conception of law.

4. Theories of Adjudication

4.1 Adjudication in Political Economy

As noted earlier the political economy strand of economic analysis of law itself contains two strands that are in tension with each other. On the one hand, the political economy strand seeks only to explain legal phenomena rather than to prescribe either the structure of legal institutions nor the content of particular legal rules. One might find within this strand of political economy a positive theory of adjudication but not a normative theory. Indeed, the positive theory advanced argues that judges seek to promote their

interests. Usually, these interests are defined as policy interests, that is, an interest to promote particular policies.

The second strand of political economy, *constitutional political economy*, does have normative aims. It assumes that political actors will act in a self-interested fashion *within* existing political institutions but that agents will act more impartially in the *design* of the political institutions within which they will work.[15] A normative theory of adjudication does emerge from this strand of political economy but it differs significantly from the normative theory endorsed by the policy analysis strand of economic analysis of law. For constitutional political economy, a normative theory of adjudication must be a structural one; it should describe the structure of adjudication. The theory thus cannot dictate directly judicial motivation because, according to political economy, judges will always act self-interestedly. Adjudicative institutions, however, can be designed to align better the interests of judges with the interests of the designer of the constitution.

In 1975, Landes and Posner offered a justification for the independence of the judiciary that is often understood as a normative theory of adjudication within the tradition of constitutional political economy. On the account of Landes and Posner, an independent judiciary serves the interest of legislators who seek to impose their policies on the jurisdiction for periods that exceed the length of their majority in the legislature. As a consequence, they find it in their interest to have the judiciary enforce the original bargain struck in all legislation.

This argument contains a normative theory of statutory interpretation. Judges ought to enforce the bargains reached by the legislature that enacted the statute. On this account, a judge ignores the views of the current legislative majority. She also eschews interpretation of the statute in terms of her own policy preferences.

One should note that, from the perspective of constitutional political economy, the argument of Landes and Posner is incomplete. They ground their theory of judicial independence in the interests of legislators. The interests of legislators within extant legislative institutions may not coincide with the interests of the constitutional designer.

4.2 Adjudication in Policy Analysis

A normative theory of adjudication was among the earliest claims advanced in the economic analysis of law. Posner [1973, 1979, 1980, 1985, 1990, 1995] asserted claim II in the introduction: the common law *ought* to be efficient. He interpreted efficiency as "wealth maximization" but then interpreted wealth maximization as "willingness to pay." This interpretive stance yielded an argument that judges in (common law) cases ought to choose the legal rule that maximized the ratio of benefits to costs as measured by the sum of individual willing nesses to pay.

Posner’s claim evoked great controversy in the late 1970s and early 1980s. (See, e.g., *Symposium* [1980]). Twenty years later, Kaplow and Shavell [2001] revived and revised Posner’s claim. The revision had two

components. First, and most important, they chose *welfarism* generally rather than cost-benefit analysis in particular as the normative basis for adjudication. Welfarism requires that evaluation depend solely on the well-being of individuals. Cost-benefit analysis is thus a form of welfarist evaluation; but Kaplow and Shavell's argument allows them to avoid various criticisms of cost-benefit analysis. Second, Kaplow and Shavell do not argue primarily for a normative theory of adjudication. Rather they contend that evaluation of legal rules and institutions by scholars ought to be welfarist. They suggest however that judges by and large have the same evaluative obligation as the third party analyst.

4.21 A brief critique of cost-benefit analysis as a theory of adjudication

Cost-benefit analysis attempts to implement a Kaldor-Hicks evaluative criterion. According to the Kaldor-Hicks criterion, a distribution of goods (broadly understood) *X* is superior to a distribution of goods *Y* if and only if there exists a third distribution of goods *Z* such that (a) *Z* is a redistribution of the distribution *X*; and (b) *Z* is Pareto preferred to *Y*.[16]

Cost-benefit analysis proceeds in two steps. First, for each individual, it identifies a particular representation of the individual's ordinal ranking of the options open to the policy maker. Second, it aggregates these representations of each individual's preferences into a social ranking.

The first step is unproblematic. Consider agent *K*. *K* has preferences over states of the world. A representation of these preferences assigns a number to each state of the world such that *K* prefers state *X* to state *Y* if and only if the number assigned to state *X* is higher than the number assigned to state *Y*. Cost-benefit analysis assigns as numbers the agent's willingness to pay. This procedure thus links the range of numbers that the agent may assign to the agent's wealth as willingness to pay is defined in part in terms of the agent's ability to pay.[17] The procedure for assigning numbers on the basis of an individual's willingness to pay in fact yields a representation of that agent's preferences.

The second step of cost-benefit analysis is more problematic. To aggregates the individual willingnesses to pay, cost-benefit analysis simply sums the individual willingnesses to pay. One can see immediately several difficulties with this procedure. First, each ranking is ordinal; the numbers have no significance beyond the order. If *K* assigns a number 2 to state *X*, a number 4 to state *Y* and a number 16 to state *Z*, we cannot conclude anything about *K*'s intensity of preference; she does not prefer *Z* to *Y* six times as much as she prefers *Y* to *X*. It therefore seems odd that one can add agent *K*'s willingness to pay to agent J's willingness to pay.

Second, cost-benefit analysis adopts a method of interpersonal comparisons of well-being that is particularly unconvincing. Interpersonal comparison of well-being requires that one identify the appropriate representation of each individual's preference ordering and compare those representations. Cost-benefit analysis however does not identify representations on moral or political grounds; rather it chooses the representations that contingently arise from the actual distribution of wealth and income in the society.[18] If Tom is poor while Bill is wealthy, it is unclear why the representations of the well-being of each that derives from willingness to pay provide interpersonally comparable measures. Equally, if

Tom and Bill are equally wealthy but Tom is disabled and Bill is not, the willingness to pay of each may still not be interpersonally comparable.

4.22 A Structural Critique of Welfarist theories of adjudication

One might construct a normative theory of adjudication at either of two levels. First, one might take as given the general structure of adjudication within a particular judicial system and ask what obligations the judges within that system ought to have. Second, one might more fundamentally design the judicial system from scratch. On this second account, the institutional environment in which judges act as well as the obligations of judges within that institutional environment would be subject to evaluation.

Most normative theories of adjudication are of the first type. They take the institutional structure in which adjudication occurs largely as given and then identify the obligations of judges within that system. Phrased differently, normative theories of adjudication are interpretive of an ongoing practice rather than efforts to design a practice from scratch. Welfarist theories of adjudication face several difficulties when understood as interpretive theories of existing (common law) practice.[19]

First, the structure of adjudication does not generally provide adequate or appropriate information for the selection of rules that maximize social welfare. Adjudication in a common law system usually focuses on a past transaction between particular parties. This transaction may not be typical of transactions that were litigated; it certainly will not be typical of the entire population of transactions that a rule would govern. Under a given rule, for instance, the set of transactions that do not lead to litigation are likely to differ systematically from the set of transactions that do give rise to litigation. Equally important, different legal rules are apt to generate different sets of transactions. The current structure of adjudication does not provide any information that would help a decision maker assess these differences across potential legal rules.

Second, the selection procedure for judges does not identify individuals with the appropriate training and background to make accurate calculations of social welfare. Judges in common law countries have generally not been trained systematically in economics and statistics, two disciplines necessary (but not sufficient) for the determination of social welfare under alternative legal rules.

Third, and related, judges usually face severe constraints in the set of legal rules they may consider in any adjudication. When confronted by a tort case, for example, the court usually considers a limited number of legal regimes; perhaps it will reformulate the standard of care or shift from a regime of negligence to one of strict liability. A court, however, is unlikely to adopt a complex scheme of no-fault insurance or to impose a different insurance scheme even though these more radical transformations of social institutions would provide higher overall welfare.

5. Evaluation of Legal Rules and Institutions

The evaluative tradition in economics is resolutely welfarist. That tradition extends to the policy analysis

branch of economic analysis of law. In the prior section, I considered the manifestation of this tradition in the advocacy of cost-benefit analysis as a normative theory of adjudication. In this section, I consider arguments for welfarism as an evaluative standard against which to appraise legal rules and institutions. Welfarism here is not advocated as a theory of adjudication. Consequently, the structural critique of section 5.22 does not apply. The argument here thus lies almost wholly on philosophic territory.

The argument for welfarism as the evaluative criterion for legal rules and institutions has two key elements.[20] The first identifies an individual's well-being with her preferences. Thus, an individual K has greater well-being in state *X* than in state *Y*, if and only if she prefers state *X* to state *Y*. The second, key element of the argument welfarism is a strategy of incorporation. The strategy of incorporation includes within the agent's preference ordering anything that the agent considers relevant to her decisions. The individual's preferences thus correspond to her all-things-considered judgments; that is, *K* prefers state *X* to state *Y* if and only if *K* believes, all things considered, that state *X* is better than (or ought to be promoted rather than) state *B*. K's all-things-considered judgments, of course, will included many considerations that, in ordinary language, are not usually considered as in *K*'s self-interest or even as contributing to her well-being. So, for example, her all-things-considered judgments will incorporate concerns for the well-being of others as well as considerations of justice and deontological constraints on action.

The success of this argument for welfarism depends on the success of this strategy of incorporation of every reason for action into an agent's preference ordering. I shall raise here two objections to this strategy of incorporation. First, the resulting extended preference ordering does not correspond to a concept of well-being that is morally compelling because not all concerns incorporated into the individual's preferences play the appropriate role in her deliberations. Second, aggregation of these extended preference orderings does not treat the moral reasons incorporated in the extended preference ordering appropriately.

A complete argument that the extended preference ordering does not correspond to a morally compelling conception of well-being would require articulation of the concept of well-being, a task well beyond the scope of this entry. For purposes of this critique, it may suffice to note the varying levels of choice at which various concerns apply. The strategy of incorporation requires that one incorporate a moral concern into an individual's extended preference ordering when that moral concern motivates an individual's choices. While it may be the case that the individual in fact prefers a world in which the given moral concern motivates to one in which it does not, the preference for the moral concern arises in the choice of institutional or social arrangements not in the choice within a given set of institutions or social arrangements. The choice within the given institutions may reduce the agent's well-being rather than promote it.

Turn now to the second objection. Even if extended preference orderings do not correspond to well-being, a defender of welfarism might argue that it is appropriate to aggregate these orderings rather than ones that capture the conception of well-being. This argument, however, misunderstands the distinction between judgment and preference.[21] Many of the concerns that enter into an agent's all-things-considered decisions are judgments rather than preferences. Appropriate techniques of aggregation of

judgment differ from those of aggregation of preferences.

Crudely, preference differs from judgment in two respect. First, an expression of preference is personal. The individual expresses a preference that is valid for her; she makes no claim about the validity of this preference for others. Liza's statement that she prefers to be a jazz musician to a lawyer makes no claims concerning Henry's preferred profession. Judgments generally have a greater scope. If Liza claims that jazz musicians contribute more to social welfare than lawyers, she is not expressing a preference that this be so; she asserts that it is true for everyone (at least within current social arrangements).

Second, an individual is sovereign over her own preferences but not over her judgments. An individual has final say over her preferences but not over her judgments. Henry's assertion that he prefers to be a lawyer rather than a jazz musician provides no reason for Liza to reconsider her statement that she prefers to be a jazz musician. If, however, Henry asserts that lawyers contribute more to social welfare than jazz musicians, Liza does have reason to reconsider her contrary judgment. Only one of them can be correct.[22]

Many of the concerns that, under the strategy of incorporation, are included in an individual's extended preference ordering sound in judgment rather than preference. Concerns for distributive justice, for example, reflect moral judgments and not expressions of preference.[23] Similarly, respect for deontological constraints on action sound in judgment not preference. Moreover, these moral judgments depend on proof and argument.

The distinction between preference and judgment points to several difficulties with this argument for welfarism . First, to the extent that individual well-being is understood subjectively, it is likely to be a matter of preference not judgment. Yet the extended preference orderings that constitute the domain of the social welfare function include judgments; this conflation of judgment and preferences provides an argument in addition to the one above that these orderings are not equivalent to well-being.

Second, the methods of aggregation of judgment are likely to differ from the methods of aggregation of preference. Rational aggregation of judgments is likely to parallel rational aggregation of belief. When individuals have different beliefs, one does not generally resolve the conflict through some simple process of aggregation.[24] Rather, the individuals pool information; then each individual updates her beliefs in light of the new information. Ideally, this process leads to convergence of belief. Similarly, the process of moral argument ideally leads to the revision of individual moral judgments.

6. Concluding Remarks

Though the controversy over economic analysis of law has waned, its project continues to disquiet many scholars who study legal phenomena. The prior discussion identifies two distinct sources for that disquiet.

Many legal scholars object to the normative theory of adjudication advanced by policy analysts. These

scholars generally reject the welfarism to which policy analysis is committed. The prior discussion suggests, however, that a rejection of welfarism as a moral theory is neither necessary nor sufficient for the rejection of the normative theory of adjudication advanced by policy analysts.

The methodology of economic analysis of law poses a more significant challenge to traditional accounts of law. Economic analysis of law provokes disquiet because the model of self-interested maximization of preferences does not admit a concept of normativity but explaining the normativity of law is a central pre-occupation of philosophy of law. The logic of this commitment to self-interested maximization of preferences would appear to lead to a denial of the need for a distinct concept of law in the explanation and evaluation of social institutions.

Notes to Economic Analysis of the Law

Notes

1. I have phrased (*V*) in Dworkinian terms. Many economic analyses of specific doctrines argue that the economic interpretation fits the doctrinal development; many also contend that efficiency is valuable. I should note, however, that "fit" here has an odd sense. The interpretive claim does not assert that the legal rules in fact are efficient. Rather, it asserts that the rules are efficient within the context of some model that one might impute to judges. The imputation, however, does not rest on an interpretation of judicial opinions.

2. Economic analyses of law include both theoretical and empirical studies. One might thus differentiate strands in terms of the nature of the theory used - game theory, simple price theory, or behavioral economics (which abandons one or more of the rationality postulates of neoclassical economic theory). Alternatively, one might differentiate strands in terms of the aim of enterprise: policy analysis vs. explanation vs prediction.

3. In many articles that explicitly address policy issues, the analyst employs cost benefit analysis. Cost-benefit analysis is often regarded as an implementation of some welfarist social objective function. For criticism of this assumption, see Kornhauser [1998, 2000].

4. The intellectual geography of political economy is actually more complex. Buchanan is a founder and exemplar of the "Virginia" school of the theory of political institutions, sometimes called "public choice theory." Its evaluative commitments are indeed contractarian. The Rochester school of the theory of political institutions, sometimes called "positive political theory," however, has not in general rejected welfarism. Both schools apply economic techniques to the analysis of political institutions and both schools have influenced the economic analysis. (One might differentiate them crudely in the following way. Public choice theory fixes political institutions and asks how the distribution of preferences within the polity affects outcomes. Positive political theory, by contrast, fixes the distribution of preferences within the polity and asks how institutional design affects outcomes.

5. Political economic accounts of adjudication will also reject a purposive account of adjudication. Even if a judge pursues a specific purpose, no judge has complete control over the development of the law. Consequently, the legal rules that evolve are unlikely to be efficient or to further the aims of a specific individual. Nor can a particular aim be attributed to the courts as a whole.

6. Institutional instrumentalism is somewhat at odds with a contractarian evaluative position. Note that one might identify a third type of legal instrumentalism, *systemic instrumentalism*, in which the legal

system as a whole promotes some goal. One might understand Durkheim's theory of law in this manner. On legal instrumentalism generally see Kornhauser [2000].

7. Some models do study the consequences of uncertainty over the legal rule and some of these models interpret this uncertainty as judicial uncertainty. The formalism, however, admits equally the interpretation that the private agent is uncertain how the court will respond to her action.

8. Obligation might enter into an economic account of behavior as a concern that the agent integrates into her preference ordering. Breach of an obligation would impose a "psychic cost" that she weighs with other costs and benefits in her decision. Though under this approach obligations motivate, it is clearly ad hoc and unsatisfactory. For further comments see Kornhauser [2000].

9. Public officials must also be infallible in the sense that they always correctly understand and implement the obligations defined by the legal order.

10. In the standard exposition of this game, there are only two players so that identification of the highest and lowest ranked alternatives gives a complete ranking. The text suggests a game with more than two players. To fill out the ranking define $n(L)$ as the number of people who drive on the left and $n(R)$ as the number of people who drive on the right. Let $m = \min\{n(L), n(R)\}$ and $M = \max\{n(L), n(R)\}$. Let $r = m/M$. The ratio r is defined for each possible choice of strategy vector. Consider two strategy vectors s and s′ with r and r′ the associated ratios. Then each agent prefers s to s′ if and only if $r < r'$.

11. That is, the rule specifies an action that is not necessarily a best response, under perfect information and costless deliberation, to the specific situation. The rule might be an optimal response to the class of situations, given costly deliberation and imperfect information.

12. See Raz [1994]. Raz, at times, seems to ground legal authority in convention; such a grounding would provide a third, economic account of authority as the analysis of convention rests on self-interest. This argument, too, fails to provide an account of authority that treats legal rules as exclusionary reasons. For a clear exposition of this argument see Green [1985].

13. In accident situations where the agents are symmetrically placed, each taking due care may be in the interests of both but, in the non-cooperative solution to this strategic situation, each would, in the absence of a legal rule, adopt a suboptimal level of care. In the prudential account, by contrast, it is in each agent's interest to follow the rule because the costs of identifying the better action exceed the gains from such efforts.

14. Heiner [1986]. This account assumes that each judge has an interest in "correctly" deciding cases. It thus assumes away the first difficulty. Rasmusen [1994] provides an equilibrium account (see below) of *stare decisis*, on the other hand, that relies only on the interest of each individual judge. Rasmusen's theory of *stare decisis*, though it grounds the practice in judicial "self-interest" (understood as the desire

to influence policy), does not yield a rule that functions as an exclusionary reason to follow the law.

15. Constitutional political economy generally argues that, even at the design phase, agents act self-interestedly. Impartiality arises not from a shift in motivation but from the difference in the environment so that self-interest coincides with a more impartial perspective. See generally Brennan and Buchanan [1981, 1985] for this argument. Brennan has subsequently rejected his earlier views in Brennan and Hamlin [2000]. For a critique, see Kornhauser [2001].

16. *Z* is pareto preferred to *Y* if and only no one in the population prefers *Y* to *Z* and at least one person prefers *Z* to *Y*. Technically, the Kaldor-Hicks criterion is not a purely welfarist critierion as it requires reference to the underlying distribution of goods and not simply the underlying distribution of well-being.

17. So if agent *K* has wealth w_K, cost benefit analysis assigns a number [-, w_K] where negative numbers indicate the amount one must pay *K* in order for her to accept that state of affairs.

18. My critique of cost-benefit analysis here is thus related to but different from the standard critique that cost-benefit analyses depend on the underlying distribution of income. That critique contends that an unjust distribution would undermine the moral legitimacy of the cost benefit analysis. The argument in the text suggests that, even if the underlying distribution of income and wealth were morally acceptable, we would require additional argument to establish that the representation of preference derived by willingness to pay would yield interpersonally comparable measures of well-being.

19. They fare no better as interpretive theories of adjudication within civil law countries. Economic analysis of law, however, has concentrated predominantly on the study of common law systems of adjudication.

20. Kaplow and Shavell [2001] offers a defense of welfarism consistent with the characterization in the text. I provide a more comprehensive discussion and critique of Kaplow and Shavell's argument in Kornhauser [2001].

21. The distinction between judgment and preference is elaborated in Kornhauser and Sager [1986] and Kornhauser [2001].

22. Henry contradicts Liza's assertion that she prefers to be a jazz musician, Liza may have reason to reconsider her expression of preference if Henry is a close acquaintance of hers. If Henry is a stranger, however, Liza may regard his assertion as an unwelcome intrusion in her affairs.

23. This claim does not rely on a cognitive view of morality. Even expressivists such as Gibbard [1990] and Blackburn [1998] acknowledge that moral assertions are not personal and that the individual has no sovereignty over them. For a fuller discussion, see Kornhauser [2001].

24. In some contexts of course majority rule is used to resolve conflict in belief but we defend this aggregation method in a different way. Compare the defense of majority rule in jury decisions to its defense in interest group theories of politics.

On The Nature of Law

Lawyers are typically interested in the question: What is *the law* on a particular issue? This is always a local question and answers to it are bound to differ according to the specific jurisdiction in which they are asked. In contrast, the philosophy of law is interested in the general question: What is Law? This general question about the nature of law presupposes that law is a unique social-political phenomenon, with more or less universal characteristics that can be discerned through philosophical analysis. General jurisprudence, as this philosophical inquiry about the nature of law is called, is meant to be universal. It assumes that law possesses certain features, and it possesses them by its very nature, or essence, as law, whenever and wherever it happens to exist. However, even if there are such universal characteristics of law, the reasons for a philosophical interest in elucidating them remain to be explained. First, there is the sheer intellectual interest in understanding such a complex social phenomenon which is, after all, one of the most intricate aspects of human culture. Law, however, is also a normative social practice: it purports to guide human behavior, giving rise to reasons for action. An attempt to explain this normative, reason-giving aspect of law is one of the main challenges of general jurisprudence. These two sources of interest in the nature of law are closely linked. Law is not the only normative domain in our culture; morality, religion, social conventions, etiquette, and so on, also guide human conduct in many ways which are similar to law. Therefore, part of what is involved in the understanding of the nature of law consists in an explanation of how law differs from these similar normative domains, how it interacts with them, and whether its intelligibility depends on such other normative orders, like morality or social conventions.

Contemporary legal theories define these two main interests in the nature of law in the following terms. First, we need to understand the general conditions which would render any putative norm legally valid. Is it, for example, just a matter of the source of the norm, such as its enactment by a particular political institution, or is it also a matter of the norm's content? This is the general question about the conditions of legal validity. Second, there is the interest in the normative aspect of law. This philosophical interest is twofold: A complete philosophical account of the normativity of law comprises both an explanatory and a normative-justificatory task. The explanatory task consists of an attempt to explain how legal norms can give rise to reasons for action, and what kinds of reasons are involved. The task of justification concerns the elucidation of the reasons people *ought* to have for acknowledging law's normative aspect. In other words, it is the attempt to explain the moral legitimacy of law. A theory about the nature of law, as opposed to critical theories of law, concentrates on the first of these two questions. It purports to explain what the normativity of law actually consists in.

Thus, elucidating the conditions of legal validity and explaining the normativity of law form the two main subjects of any general theory about the nature of law. In the course of the last few centuries, two

main rival philosophical traditions have emerged, providing different answers to these questions. The older one, dating back to late mediaeval Christian scholarship, is called the natural law tradition. Since the early 19th century, Natural Law theories have been fiercely challenged by the legal positivism tradition promulgated by such scholars as Jeremy Bentham and John Austin. The philosophical origins of Legal Positivism are much earlier, though, probably in the political philosophy of Thomas Hobbes. The main controversy between these two traditions concerns the conditions of legal validity. Basically, Legal Positivism asserts, and Natural Law denies, that the conditions of legal validity are purely a matter of social facts. In contrast to Positivism, Natural Law claims that the conditions of legal validity are not exhausted by social facts; the moral content of the putative norms also bears on their legal validity. As the famous dictum of Saint Augustine has it: '*lex iniusta non est lex*' (unjust law is not law).

The Conditions of Legal Validity

The main insight of Legal Positivism, that the conditions of legal validity are determined by social facts, involves two separate claims which have been labeled The Social Thesis and The Separation Thesis. The Social Thesis asserts that law is, profoundly, a social phenomenon, and that the conditions of legal validity consist of social facts. Early Legal Positivists followed Hobbes' insight that the law is, essentially, an instrument of political sovereignty, and they maintained that the basic source of legal validity resides in the facts constituting political sovereignty. Law, they thought, is basically the command of the sovereign. Later legal Positivists have modified this view, maintaining that social conventions, and not the facts about sovereignty, constitute the grounds of law. Most contemporary legal Positivists share the view that there are conventional rules of recognition, namely, social conventions which determine certain facts or events that provide the ways for the creation, modification, and annulment of legal standards. These facts, such as an act of legislation or a judicial decision, are the *sources of law* conventionally identified as such in each and every modern legal system.

Natural lawyers deny this insight, insisting that a putative norm cannot become legally valid unless it passes a certain threshold of morality. Positive law must confirm in its content to some basic precepts of Natural Law, that is, universal morality, in order to become law in the first place. In other words, Natural Lawyers maintain that the moral content of norms, and not just their social origins, also form part of the conditions of legal validity.

The Separation Thesis is an important negative implication of this Social Thesis, maintaining that there is

a conceptual separation between law and morality, that is, between what the law is, and what the law ought to be. The Separation Thesis, however, has often been overstated. It is sometimes thought that Natural Law asserts, and Legal Positivism denies, that the law is, by necessity, morally good or that the law must have some minimal moral content. The Social Thesis certainly does not entail the falsehood of the assumption that there is something necessarily good in the law. Legal Positivism can accept the claim that law is, by its very nature or its essential functions in society, something good that deserves our moral appreciation. Nor is Legal Positivism forced to deny the plausible claim that wherever law exists, it would have to have a great many prescriptions which coincide with morality. There is probably a considerable overlap, and perhaps necessarily so, between the actual content of law and morality. Once again, the Separation Thesis, properly understood, pertains only to the conditions of legal validity. It asserts that the conditions of legal validity do not depend on the moral content of the norms in question. What the law is cannot depend on what it ought to be in the relevant circumstances.

Many contemporary legal Positivists would not subscribe to this formulation of the Separation Thesis. A contemporary school of thought, called Inclusive Legal Positivism, endorses the Social Thesis, namely, that the basic conditions of legal validity derive from social facts, such as social rules or conventions which happen to prevail in a given community. But, Inclusive Legal Positivists maintain, legal validity is sometimes a matter of the moral content of the norms, depending on the particular conventions that happen to prevail in any given community. Those social conventions on the basis of which we identify the law may, but need not, contain reference to moral content as a condition of legality.

The NaturaLaw tradition has undergone a considerable refinement in the 20th century, mainly because its classical, popular version faced an obvious objection about its core insight: Basically, it is just difficult to maintain that morally bad law is not law. The idea that law must pass, as it were, a kind of moral filter in order to count as law strikes most jurists as incompatible with the legal world as we know it. Therefore, contemporary Natural Lawyers have suggested different and more subtle interpretations of the main tenets of Natural Law. For example, John Finnis views Natural Law (in its Thomist version) not as a constraint on the legal validity of positive laws, but mainly as an elucidation of an ideal of law in its fullest, or highest sense, concentrating on the ways in which law necessarily promotes the common good. As we have noted earlier, however, it is not clear that such a view about the necessary moral content of law is at odds with the main tenets of Legal Positivism.

The idea that the conditions of legal validity are at least partly a matter of the moral content of the norms is articulated in a sophisticated manner by Ronald Dworkin's legal theory. Dworkin is not a classical Natural Lawyer, however, and he does not maintain that morally acceptable content is a precondition of a norm's legality. His core idea is that the very distinction between facts and values in the legal domain, between what the law is and what it ought to be, is much more blurred than Legal Positivism would have it: Determining what the law is in particular cases inevitably depends on moral-political considerations about what it ought to be. Evaluative judgments partly determine what the law is.

Dworkin's legal theory is not based on a general repudiation of the classical fact-value distinction, as much as it is based on a certain conception of legal reasoning. This conception went through two main stages. In the 1970's Dworkin argued that the falsehood of Legal Positivism resides in the fact that it is

incapable of accounting for the important role that legal principles play in determining what the law is. Legal positivism envisaged, Dworkin claimed, that the law consists of rules only. However, this is a serious mistake, since in addition to rules, law is partly determined by legal principles. The distinction between rules and principles is basically a logical one. Rules, Dworkin maintained, apply in an 'all or nothing fashion'. If the rule applies to the circumstances, it determines a particular legal outcome. If it does not apply, it is simply irrelevant to the outcome. On the other hand, principles do not determine an outcome even if they clearly apply to the pertinent circumstances. Principles basically provide the judges with a reason to decide the case one way or the other, and hence they only have a dimension of weight. That is, the reasons provided by the principle may be relatively strong, or weak, but they are never 'absolute'. Such reasons, by themselves, cannot determine an outcome, as rules do.

The most interesting, and from a Positivist perspective, most problematic, aspect of legal principles, however, consists in their moral dimension. According to Dworkin's theory, unlike legal rules, which may or may not have something to do with morality, principles are essentially moral in their content. It is, in fact, partly a moral consideration which determines whether a legal principle exists or not. Why is that? Because a legal principle exists, according to Dworkin, if the principle follows from the best moral and political interpretation of past judicial and legislative decisions in the relevant domain. In other words, legal principles occupy an intermediary space between legal rules and moral principles. Legal rules are posited by recognized institutions and their validity derives from their enacted source. Moral principles are what they are due to their content, and their validity is purely content dependent. Legal principles, on the other hand, gain their validity from *a combination* of source-based and content-based considerations. As Dworkin put it in the most general terms: 'According to law as integrity, propositions of law are true if they figure in or follow from the principles of justice, fairness, and procedural due process that provide the best constructive interpretation of the community's legal practice.' (*Law's Empire*, at p. 225) The validity of a legal principle then, derives, from a combination of facts and moral considerations. The facts concern the past legal decisions which have taken place in the relevant domain, and the considerations of morals and politics concern the ways in which those past decisions can best be accounted for by the correct moral principles.

Needless to say, if such an account of legal principles is correct, the separation thesis can no longer be maintained. But many legal philosophers doubt that there are legal principles of the kind Dworkin envisaged. There is an alternative, more natural way to account for the distinction between rules and principles in the law: the relevant difference concerns the level of generality, or vagueness, of the norm-act prescribed by the pertinent legal norm. Legal norms can be more or less general, or vague, in their definition of the norm-act prescribed by the rule, and the more general or vague they are, the more they tend to have those quasi-logical features Dworkin attributes to principles.

In the 1980's Dworkin radicalized his views about these issues, striving to ground his anti-positivist legal theory on a general theory of interpretation, and emphasizing law's profound interpretative nature. Despite the fact that Dworkin's interpretative theory of law is extremely sophisticated and complex, the essence of his argument from interpretation can be summarized in a rather simple way. The main argument consists of two main premises. The first thesis maintains that determining what the law requires in each and every particular case necessarily involves an interpretative reasoning. Any statement

of the form "According to the law in S, *x* has a right/duty etc., to *y*" is a *conclusion* of some interpretation or other. Now, according to the second premise, interpretation always involves evaluative considerations. More precisely, perhaps, interpretation is neither purely a matter of determining facts, nor is it a matter of evaluative judgment *per se*, but an inseparable mixture of both. Clearly enough, one who accepts both these theses must conclude that the separation thesis is fundamentally flawed. If Dworkin is correct about both theses, it surely follows that determining what the law requires *always* involves evaluative considerations.

Both of Dworkin's two theses are highly contestable. Some legal philosophers have denied the first premise, insisting that legal reasoning is not as thoroughly interpretative as Dworkin assumes. Interpretation, according to this view, is an exception to the standard understanding of language and communication, rendered necessary only when the law is, for some reason, unclear. However, in most standard instances, the law can simply be understood, and applied, without the mediation of interpretation. Other legal philosophers denied the second premise, challenging Dworkin's thesis that interpretation is necessarily evaluative.

Dworkin's legal theory shares certain insights with the Inclusive version of Legal Positivism. Note, however, that although both Dworkin and Inclusive Legal Positivists share the view that morality and legal validity are closely related, they differ on the grounds of this relationship. Dworkin maintains that the dependence of legal validity on moral considerations is an *essential* feature of law which basically derives from law's profoundly interpretative nature. Inclusive Positivism, on the other hand, maintains that such a dependence of legal validity on moral considerations is a contingent matter; it does not derive from the nature of law or of legal reasoning as such. Inclusive Positivists claim that moral considerations affect legal validity only in those cases which follow from the social conventions which happen prevail in a given legal system. In other words, the relevance of morality is determined in any given legal system by the contingent content of that society's conventions. As opposed to both these views, traditional, or as it is now called, Exclusive Legal Positivism maintains that a norm is never rendered legally valid in virtue of its moral content. Legal validity, according to this view, is entirely dependent on the conventionally recognized factual sources of law.

It may be worth noting that those legal theories maintaining that legal validity partly depends on moral considerations must also share a certain view about the nature of morality. Namely, they must hold an objective stance with respect to the nature of moral values. Otherwise, if moral values are not objective and legality depends on morality, legality would also be rendered subjective, posing serious problems for the question of how to identify what the law is. Some legal theories, however, do insist on the subjectivity of moral judgements, thus embracing the skeptical conclusions which follow about the nature of law. According to these skeptical theories, law is, indeed, profoundly dependent on morality, but, as these theorists assume that morality is entirely subjective, it only demonstrates how the law is also profoundly subjective, always up for grabs, so to speak. This skeptical approach, fashionable in so called post-modernist literature, crucially depends on a subjectivist theory of values, which is rarely articulated in this literature in any sophisticated way.

The Normativity of Law

Throughout human history the law has been known as a coercive institution, enforcing its practical demands on its subjects by means of threats and violence. This conspicuous feature of law made it very tempting for some philosophers to assume that the normativity of law resides in its coercive aspect. Even within the legal positivist tradition, however, the coercive aspect of the law has given rise to fierce controversies. Early legal Positivists, such as Bentham and Austin, maintained that coercion is an *essential* feature of law, distinguishing it from other normative domains. Legal Positivists in the 20th century have tended to deny this, claiming that coercion is neither essential to law, nor, actually, pivotal to the fulfillment of its functions in society.

There are several issues entangled here, and we should carefully separate them. John Austin famously maintained that each and every legal norm, as such, must comprise a threat backed by sanction. This involves at least two separate claims: In one sense, it can be understood as a thesis about the concept of law, maintaining that what we call ‘law’ can only be those norms which are backed by sanctions of the political sovereign. In a second, though not less problematic sense, the intimate connection between the law and the threat of sanctions is a thesis about the normativity of law. Basically, it is a reductionist thesis, maintaining that the normativity of law consists in the subjects' ability to predict the chances of incurring punishment or evil.

In addition to this particular controversy, there is the further question, concerning the relative importance of sanctions for the ability of law to fulfill its social functions. *Hans Kelsen*, for instance, maintained that the monopolization of violence in society, and the law's ability to impose its demands by violent means, is the most important of law's functions in society. Twentieth century legal Positivists, like H.L.A. Hart and Joseph Raz, deny this, maintaining that the coercive aspect of law is much more marginal than their predecessors assumed. Once again, the controversy here is actually twofold: is coercion *essential* to what the law does? And even if it is not deemed essential, how important it is, compared with the other functions law fulfils in our lives?

Austin's reductionist account of the normativity of law, maintaining that the normative aspect of law simply consists in the subjects' ability to predict sanctions, was discussed extensively, and fiercely criticized, by H.L.A. Hart. Hart's fundamental objection to Austin's reductionist account of law's normativity is, on his own account, ‘that the predictive interpretation obscures the fact that, where rules exist, deviations from them are not merely grounds for prediction that hostile reactions will follow.... but are also a reason or justification for such reaction and for applying the sanctions.’ (*The Concept of Law*, at p. 82) This emphasis on the reason-giving function of rules is surely correct, but perhaps not enough. Supporters of the predictive account could claim that it only begs the further question of *why* people should regard the rules of law as reasons or justifications for actions. If it is, for example, *only* because the law happens to be an efficient sanction-provider, then the predictive model of the normativity of law may turn out to be correct after all. In other words, Hart's fundamental objection to the predictive model is actually a result of his vision about the main functions of law in society, holding, contra Austin and Kelsen, that those functions are not exclusively related to the ability of the law to impose sanctions.

It is arguable, however, that law's functions in our culture are more closely related to its coercive aspect than Hart seems to have assumed. Contemporary use of ‘game theory’ in the law tends to show that the rationale of a great variety of legal arrangements can be best explained by the function of law in solving problems of opportunism, like the so called Prisoner's Dilemma situations. In these cases, the law's main role is, indeed, one of providing coercive measures. Be this as it may, we should probably refrain from endorsing Austin's or Kelsen's position that providing sanctions is law's only function in society. Solving recurrent and multiple coordination problems, setting standards for desirable behavior, proclaiming symbolic expressions of communal values, resolving disputes about facts, and such, are important functions which the law serves in our society, and those have very little to do with law's coercive aspect and its sanction-providing functions.

The extent to which law can actually guide behavior by providing its subjects with reasons for action has been questioned by a very influential group of legal scholars in the first half of the 20th century, called the Legal Realism school. American Legal Realists claimed that our ability to predict the outcomes of legal cases on the basis of the rules of law is rather limited. In the more difficult cases which tend to be adjudicated in the appellant courts, legal rules, by themselves, are radically indeterminate as to the outcome of the cases. The Legal Realists thought that lawyers who are interested in the predictive question of what the courts will actually decide in difficult cases need to engage in sociological and psychological research, striving to develop theoretical tools which would enable us to predict legal outcomes. Thus Legal Realism was mainly an attempt to introduce the social sciences into the domain of jurisprudence for predictive purposes. To what extent this scientific project succeeded is a matter of controversy. Be this as it may, Legal Realism paid very little attention to the question of the normativity of law, that is, to the question of how the law does guide behavior in those cases in which it seems to be determinate enough.

A much more promising approach to the normativity of law is found in Joseph Raz's theory of authority, which also shows how such a theory about the normativity of law entails important conclusions with respect to the conditions of legal validity. The basic insight of Raz's argument is that the law is an authoritative social institution. The law, Raz claims, is a *de facto* authority. However, it is also essential to law that it must be held to claim legitimate authority. Any particular legal system may fail, of course, in its fulfillment of this claim. But the law is the kind of institution which necessarily claims to be a legitimate authority.

According to Raz, the essential role of authorities in our practical reasoning is to mediate between the putative subjects of the authority and *the right reasons* which apply to them in the relevant circumstances. An authority is legitimate only if its putative subjects are likely to comply better with the relevant reasons which apply to them by following the authoritative resolution than by trying to figure out or act on those reasons by themselves.

Now, it follows that for something to be able to claim legitimate authority, it must be of *the kind of thing* capable of claiming it, namely, capable of fulfilling such a mediating role. What kinds of things can claim legitimate authority? There are at least two such features necessary for authority-capacity: First, for

something to be able to claim legitimate authority, it must be the case that its directives are *identifiable* as authoritative directives, without the necessity of relying on those same reasons which the authoritative directive replaces. If this condition is not met, namely, if it is impossible to identify the authoritative directive as such without relying on those same reasons the authority was meant to rely on then the authority could not fulfill its essential, mediating role. In short, it could not make the practical difference it is there to make. Note that this argument does not concern the efficacy of authorities. The point is not that unless authoritative directives can be recognized as such, authorities could not function effectively. The argument is based on the rationale of authorities within our practical reasoning. Authorities are there to make a practical difference, and they could not make such a difference unless the authority's directive can be recognized as such without recourse to the reasons it is there to decide upon. In other words, it is nonsensical to have authorities if, to discover what is an authority and what is not, you have to engage in the same reasoning process that reliance on the authority is supposed to replace. Secondly, for something to be able to claim legitimate authority, it must be capable of forming an opinion on how its subjects ought to behave, distinct from the subjects' own reasoning about their reasons for action. In other words, a practical authority, like law, must be basically personal authority, in the sense that there cannot be an authority without an author.

Raz's conception of legal authority provides very strong support for Exclusive Legal Positivism since it requires that the law, *qua* an authoritative resolution, be identifiable on its own terms, that is, without having to rely on those same considerations which the law is there to settle. Therefore a norm is legally valid (i.e. authoritative) only if its validity does not derive from moral or other evaluative considerations about which it is there to settle. Notably, Raz's theory challenges both Dworkin's anti-positivist legal theory, and the Inclusive version of Legal Positivism. This challenge, and the controversies it gave rise to, form one of the main topics discussed in contemporary general jurisprudence.

Explaining the rationale of legal authority, however, is not the only component of a theory about the normativity of law. If we hold the Legal Positivist thesis that law is essentially founded on social conventions, another important question arises here: how can a conventional practice give rise to reasons for action and, in particular, to obligations? Some legal philosophers claimed that conventional rules cannot, by themselves, give rise to obligations. As Leslie Green observed, Hart's ‘view that the fundamental rules [of recognition] are ‘mere conventions’ continues to sit uneasily with any notion of obligation’, and this Green finds troubling, because the rules of recognition point to the ‘sources that judges are *legally* bound to apply.’ (‘The Concept of Law Revisited’, at p. 1697) The debate here is partly about the conventional nature of the rules of recognition, and partly about the ways in which conventions can figure in our reasons for action. According to one influential theory, inspired by David Lewis, conventional rules emerge as solutions to multiply and recurrent coordination problems. If the rules of recognition are, indeed, of such a coordination kind, it is relatively easy to explain how they may give rise to obligations. Coordination conventions would be obligatory if the norm subjects have an obligation to solve the coordination problem which initially gave rise to the emergence of the relevant convention. It is doubtful, however, that coordination conventions are at the foundations of law. In certain respects the law may be more like a structured game, or an artistic genre, which are actually constituted by social conventions. Such constitutive conventions are not explicable as solutions to some pre-existing recurrent coordination problem. The conventional rules constituting the game of chess, for

example, are not there to solve a coordination problem between potential players. Antecedent to the game of chess, there was no particular coordination problem to solve. The conventional rules of chess constitute the game itself as a kind of social activity people would find worthwhile engaging in. The constitutive conventions partly constitute the values inherent in the emergent social practice. Such values, however, are only there for those who care to see them. Constitutive conventions, by themselves, cannot ground an obligation to engage in the practice they constitute.

From a moral point of view, the rules of recognition, by themselves, cannot be regarded as sources of obligation to follow the law. Whether judges, or anybody else, should or should not respect the rules of recognition of a legal system, is basically a moral issue, that can only be resolved by moral arguments (concerning the age old issue of political obligation). And this is more generally so: the existence of a social practice, in itself, does not provide anyone with an obligation to engage in the practice. The rules of recognition only define what the practice is, and they can say nothing on the question of whether one should or should not engage in it. But of course, once one does engage in the practice, playing the judge, as it were, there are *legal* obligations defined by the rules of the game. In other words, there is nothing special in the idea of a *legal* obligation to follow the rules of recognition. The judge in a soccer game is equally obliged to follow the rules of his game, and the fact that the game is conventional poses no difficulty from this, let us say, ‘internal-player's’ perspective. But again, the constitutive rules of soccer cannot settle for anyone the question of whether they should play soccer or not. Similarly, the rules of recognition cannot settle for the judge, or anyone else for that matter, whether they should play by the rules of law, or not. They only tell the judges what the law *is*. Unlike chess or soccer, however, the law may well be a kind of game that people have an obligation to play, as it were. But if there is such an obligation, it must emerge from external, moral, considerations, that is, from a general moral obligation to obey the law. The complex question of whether there is such a general obligation to obey the law, and whether it depends on certain features of the relevant legal system, is extensively discussed in the literature on political obligation. A complete theory about the normativity of law must encompass these moral issues as well.

John Austin

John Austin is considered by many to be the creator of the school of analytical jurisprudence, as well as, more specifically, the approach to law known as "legal positivism." Austin's particular command theory of law has been subject to pervasive criticism, but its simplicity gives it an evocative power that cannot be ignored.

1. Life

John Austin's life (1790-1859) was filled with disappointment and unfulfilled expectations. His influential friends (who included Jeremy Bentham, James Mill, John Stuart Mill and Thomas Carlyle) were impressed by his intellect and his conversation, and predicted he would go far. However, in public dealings, Austin's nervous disposition, shaky health, tendency towards melancholy, and perfectionism combined to end quickly careers at the Bar, in academia, and in government service. (Hamburger 1985, 1992)

Austin was born to a Suffolk merchant family, and served briefly in the military before beginning his legal training. He was called to the Bar in 1818, but he took on few cases, and quit the practice of law in 1825. Austin shortly thereafter obtained an appointment to the first Chair of Jurisprudence at the recently established University College London. He prepared for his lectures by study in Bonn, and evidence of the influence of continental legal and political ideas can be found scattered throughout Austin's writings.

Lectures from the course he gave were eventually published in 1832 as "Province of Jurisprudence

Determined." (Austin 1995) However, attendance at his courses was small and getting smaller, and he gave his last lecture in 1833. A short-lived effort to give a similar course of lectures at the Inner Temple met the same result. Austin resigned his University College London Chair in 1835. He later briefly served on the Criminal Law Commission, and as a Royal Commissioner to Malta, but he never found either success or contentment. He did some occasional writing on political themes, but his plans for longer works never came to anything during his lifetime, due apparently to some combination of perfectionism, melancholy, and writer's block. His changing views on moral, political, and legal matters also apparently hindered both the publication of a revised edition of "Province of Jurisprudence Determined," and the completion of a longer project started when his views had been different.

Much of whatever success Austin found during his life, and after, must be attributed to his wife Sarah, for her tireless support, both moral and economic (during the later years of their marriage, they lived primarily off her efforts as a translator and reviewer), and her work to publicize his writings after his death (including the publication of a more complete set of his Lectures on Jurisprudence) (Austin 1873).

While Austin's work was influential in the decades after his death, its impact seemed to subside substantially by the beginning of the twentieth century. A significant portion of Austin's current reputation derives from H.L.A. Hart's use (1958, 1994) of Austin's theory as a foil for the explanation of Hart's own, more nuanced approach to legal theory. In recent decades some theorists have revisited Austin's work, offering new characterizations and defenses of his ideas (e.g., Morison 1982, Rumble 1985).

2. Analytical Jurisprudence and Legal Positivism

Early in his career, Austin came under the influence of Jeremy Bentham, and Bentham's utilitarianism is evident (though with some differences) in the work for which Austin is best known today. On Austin's reading of utilitarianism, Divine will is equated with Utilitarian principles: "utility is the index to the law of God ... . To make a promise which general utility condemns, is an offense against the law of God" (Austin 1873: Lecture VI, p. 307; see also Austin 1995: Lecture II, p. 41). This particular reading of utilitarianism, however, has had little long-term influence, though it seems to have been the part of his work that received the most attention in his own day (Rumble 1995: p. xx). Austin early on shared many of the ideas of the Benthamite philosophical radicals; he was "a strong proponent of modern political economy, a believer in Hartleian metaphysics, and a most enthusiastic Malthusian." (Rumble 1985: pp. 16-17)

Austin's importance to legal theory lies elsewhere -- his theorizing about law was novel at three different levels of generality. First, he was arguably the first writer to approach the theory of law analytically (as contrasted with approaches to law more grounded in history or sociology, or arguments about law which were secondary to more general moral and political theories). Analytical jurisprudence emphasizes the analysis of key concepts, including "law," "(legal) right," "(legal) duty," and "legal validity." Though analytical jurisprudence has been challenged by some in recent years (e.g., Leiter 1998), it remains the dominant approach to discussing the nature of law. Analytical jurisprudence, an approach to theorizing about law, has sometimes been confused with what the American legal realists (an influential group of

theorists prominent in the early decades of the 20th century) called "legal formalism" -- a narrow approach to how judges should decide cases. The American legal realists saw Austin in particular, and analytical jurisprudence in general, as their opponents in their critical and reform-minded efforts. In this, the realists were simply mistaken; unfortunately, it is a mistake that can still be found in some contemporary legal commentators.

(There is some evidence that Austin's views later in his life may have moved away from analytical jurisprudence towards something more approximating the historical jurisprudence school. (Hamburger 1985: pp. 178-91))

Second, within analytical jurisprudence, Austin was the first systematic exponent of a view of law known as "legal positivism." Most of the important theoretical work on law prior to Austin had treated jurisprudence as though it were merely a branch of moral theory or political theory: asking how should the state govern? (and when were governments legitimate?), and under what circumstances did citizens have an obligation to obey the law? Austin specifically, and legal positivism generally, offered a quite different approach to law: as an object of "scientific" study, dominated neither by prescription nor by moral evaluation. Subtle jurisprudential questions aside, Austin's efforts to treat law systematically gained popularity in the late 19th century among English lawyers who wanted to approach their profession, and their professional training, in a more serious and rigorous manner (Cotterrell 1989: pp. 79-81).

Legal positivism asserts (or assumes) that it is both possible and valuable to have a morally neutral descriptive (or "conceptual" -- though this is not a term Austin used) theory of law. (The main competitor to legal positivism, in Austin's day as in our own, has been natural law theory.) Legal positivism does not deny that moral and political criticism of legal systems are important, but insists that a descriptive or conceptual approach to law is valuable, both on its own terms and as a necessary prelude to criticism.

There were theorists prior to Austin who arguably offered views similar to legal positivism or who at least foreshadowed legal positivism in some way. Among these would be Thomas Hobbes, with his amoral view of laws as the product of Leviathan (Hobbes 1996); David Hume, with his argument for separating "is" and "ought" (which worked as a sharp criticism for some forms of natural law theory, which purported to derive moral truths from statements about human nature) (Hume 2000); and Jeremy Bentham, with his attacks on judicial lawmaking and on those, like Sir William Blackstone, who justified such lawmaking with natural-law-like justifications (Bentham 1970, 1996).

Austin's famous formulation of what could be called the "dogma" of legal positivism is as follows:

> The existence of law is one thing; its merit or demerit is another. Whether it be or be not is one enquiry; whether it be or be not conformable to an assumed standard, is a different enquiry. A law, which actually exists, is a law, though we happen to dislike it, or though it vary from the text, by which we regulate our approbation and disapprobation. (Austin 1995: Lecture V, p. 157)

Third, Austin's version of legal positivism, a "command theory of law" (which will be detailed in the next

section) has also been influential. Austin's theory had similarities with the views developed by Jeremy Bentham, whose theory could also be characterized as a "command theory." However, Austen's work was more influential in this area, because Bentham's jurisprudential writings did not appear in an even-roughly systematic form until well after Austin's work had already been published. (Bentham 1970, 1996; Cotterrell 1989: pp. 52-53)

3. Austin's Views

Austin's basic approach was to ascertain what can be said generally, but still with interest, about all laws. Austin's analysis can be seen as either a paradigm of, or a caricature of, analytical philosophy, in that his discussions are dryly full of distinctions, but are thin in argument. The modern reader is forced to fill in much of the meta-theoretical, justificatory work, as it cannot be found in the text. Where Austin does articulate his methodology and objective, it is a fairly traditional one: he "endeavored to resolve a *law* (taken with the largest signification which can be given to that term *properly*) into the necessary and essential elements of which it is composed." (Austin 1995: Lecture V, p. 117)

As to what is the core nature of law, Austin's answer is that laws ("properly so called") are commands of a sovereign. He clarifies the concept of positive law (that is, man-made law) by analyzing the constituent concepts of his definition, and by distinguishing law from other concepts that are similar:

- "Commands" involve an expressed wish that something be done, and "an evil" to be imposed if that wish is not complied with.
- Rules are general commands (applying generally to a class), as contrasted with specific or individual commands ("drink wine today" or "John Major must drink wine").
- Positive law consisted of those commands laid down by a sovereign (or its agents), to be contrasted to other law- givers, like God's general commands, and the general commands of an employer.
- The "sovereign" was defined as a person (or collection of persons) who receives habitual obedience from the bulk of the population, but who does not habitually obey any other (earthly) person or institution. Austin thought that all independent political societies, by their nature, have a sovereign.
- Positive law should also be contrasted with "laws by a close analogy" (which includes positive morality, laws of honor, international law, customary law, and constitutional law) and "laws by remote analogy" (e.g., the laws of physics).
  (Austin 1995: Lecture I).

Austin also wanted to include within "the province of jurisprudence" certain "exceptions," items which did not fit his criteria but should nonetheless be studied with other "laws properly so called": repealing laws, declarative laws, and "imperfect laws" - laws prescribing action but without sanctions (a concept Austin ascribes to "Roman [law] jurists"). (Austin 1995: Lecture I, p. 36)

In the criteria set out above, Austin succeeded in delimiting law and legal rules from religion, morality,

convention, and custom. However, also excluded from "the province of jurisprudence" were customary law (except to the extent that the sovereign had, directly or indirectly, adopted such customs as law), public international law, and parts of constitutional law. (These exclusions alone would make Austin's theory problematic for most modern readers.)

Within Austin's approach, whether something is or is not "law" depends on which people have done what: the question turns on an empirical investigation, and it is a matter mostly of power, not of morality. Of course, Austin is not arguing that law should not be moral, nor is he implying that it rarely is. Austin is not playing the nihilist or the skeptic. He is merely pointing out that there is much that is law that is not moral, and what makes something law does nothing to guarantee its moral value. "The most pernicious laws, and therefore those which are most opposed to the will of God, have been and are continually enforced as laws by judicial tribunals." (Austin 1995: Lecture V, p. 158).

In contrast to his mentor Bentham, Austin had no objection to judicial lawmaking, which Austin called "highly beneficial and even absolutely necessary." (Austin, 1995: Lecture V, p. 163) Nor did Austin find any difficulty incorporating judicial lawmaking into his command theory: he characterized that form of lawmaking, along with the occasional legal/judicial recognition of customs by judges, as the "tacit commands" of the sovereign, the sovereign's affirming the "orders" by its acquiescence. (Austin 1995: Lecture 1, pp. 35-36).

4. Criticisms

As many readers come to Austin's theory mostly through its criticism by other writers (prominently, that of H.L.A. Hart), the weaknesses of the theory are almost better known than the theory itself:

- In many societies, it is hard to identify a "sovereign" in Austin's sense of the word (a difficulty Austin himself experienced, when he was forced to describe the British "sovereign" awkwardly as the combination of the King, the House of Lords, and all the electors of the House of Commons). Additionally, a focus on a "sovereign" makes it difficult to explain the continuity of legal systems: a new ruler will not come in with the kind of "habit of obedience" that Austen sets as a criterion for a system's rule-maker. However, one could argue (see Harris 1977) that the sovereign is best understood as a constructive metaphor: that law should be viewed as if it reflected the view of a single will (a similar view, that law should be interpreted as if it derived from a single will, can be found in Ronald Dworkin's work (1986)).
- A "command" model seems to fit some aspects of law poorly (e.g., rules which grant powers to officials and to private citizens - of the latter, the rules for making wills, trusts, and contracts are examples), while excluding other matters (e.g., international law) which we are not inclined to exclude in the category "law."
- More generally, it seems more distorting than enlightening to reduce all law to one type. For example, rules that empower people to make wills and contracts perhaps can be re-characterized as part of a long chain of reasoning for eventually imposing a sanction (Austin spoke in this context of the sanction of "nullity") on those who fail to comply with the relevant provisions. However,

such a re-characterization this misses the basic purpose of those sorts of laws - they are arguably about granting power and autonomy, not punishing wrongdoing.
- A theory which portrays law solely in terms of power fails to distinguish rules of terror from forms of governance sufficiently just that they are accepted as legitimate by their own citizens.

(Austin was aware of some of these lines of attack, and had responses ready; it is another matter whether his responses were adequate.) It should also be noted that Austin's work shows a silence on questions of methodology, though this may be forgivable, given the early stage of jurisprudence. As discussed in an earlier section, in many ways, Austin was blazing a new path.

When H.L.A. Hart revived legal positivism in the middle of the 20th century (Hart 1958, 1994), he did it by criticizing and building on Austin's theory: for example, Hart's theory did not try to reduce all laws to one kind of rule, but emphasized the varying types and functions of legal rules; and Hart's theory, grounded partly on the distinction between "obligation" and "being obliged," was built around the fact that some participants within legal systems "accepted" the legal rules as reasons for action, above and beyond the fear of sanctions.

5. A Revisionist View?

Some modern commentators appreciate in Austin elements that were probably not foremost in his mind (or that of his contemporary readers). For example, one occasionally sees Austin portrayed as the first "realist": in contrast both to the theorists that came before Austin and to some modern writers on law, Austin is seen as having a keener sense of the connection of law and power, and the importance of keeping that connection at the forefront of analysis. (cf. Cotterrell 1989: pp. 57-79) When circumstances seem to warrant a more critical, skeptical or cynical approach to law and government, Austin's equation of law and force will be attractive - however distant such a reading may be from Austin's own liberal-utilitarian views at the time of his writing, and his even more conservative political views later in his life. (Hamburger, 1985)

Well Being

Well-being is most commonly used in philosophy to describe what is non-instrumentally or ultimately good *for* a person. The question of what well-being consists in is of independent interest, but it is of great importance in moral philosophy, especially in the case of utilitarianism, according to which well-being is to be maximized. Signficant challenges to the very notion have been made, in particular by G.E. Moore and T.M. Scanlon. It has become standard to distinguish theories of well-being as either hedonist theories, desire theories, or objective list theories. According to the view known as welfarism, well-being is the only value. Also important in ethics is the question of how a person's moral character relates to their well-being.

1. The Concept

Popular use of the term 'well-being' usually relates to health. A doctor's surgery may run a 'Women's Well-being Clinic', for example. Philosophical use is broader, but related, and amounts to the notion of how well a person's life is going for that person. A person's well-being is what is 'good for' them. Health, then, might be said to be a constituent of my well-being, but it is not plausibly taken to be all that matters for my well-being. One correlate term worth noting here is 'self-interest': my self-interest is what

is in the interest of myself, and not others.

The philosophical use of the term also tends to encompass the ‘negative’ aspects of how a person’s life goes for them. So we may speak of the well-being of someone who is, and will remain in, the most terrible agony: their well-being is negative, and such that their life is worse for them than no life at all. The same is true of closely allied terms, such as ‘welfare’, which covers how a person is faring as a whole, whether well or badly, or ‘happiness’, which can be understood -- as it was by the classical utilitarians from Jeremy Bentham onwards, for example -- to be the balance between good and bad things in a person’s life. But note that philosophers also use such terms in the more standard ‘positive’ way, speaking of ‘ill-being’, ‘ill-faring’, or, of course, ‘unhappiness’ to capture the negative aspects of individuals’ lives.

‘Happiness’ is often used, in ordinary life, to refer to a short-lived state of a person, frequently a feeling of contentment: ‘You look happy today’; ‘I’m very happy for you’. Philosophically, its scope is more often wider, encompassing a whole life. And in philosophy it is possible to speak of the happiness of a person’s life, or of their happy life, even if that person was in fact usually pretty miserable. The point is that some good things in their life made it a happy one, even though they lacked contentment.

When discussing the notion of what makes life good for the individual living that life, it is preferable to use the term ‘well-being’ instead of ‘happiness’. For we want at least to allow conceptual space for the possibility that, for example, the life of a plant may be ‘good for’ that plant. And speaking of the happiness of a plant would be stretching language too far. (An alternative here might be ‘flourishing’, though this might be taken to bias the analysis of human well-being in the direction of some kind of natural teleology.) In that respect, the Greek word commonly translated ‘happiness’ (*eudaimonia*) might be thought to be superior. But, in fact, *eudaimonia* seems not only to have been restricted to conscious beings, but to human beings: animals cannot be *eudaimon*. This is because *eudaimonia* suggests that the gods, or fortune, have favoured one, and the idea that the gods could care about non-humans would not have occurred to most Greeks.

It is occasionally claimed that certain ancient ethical theories, such as Aristotle’s, result in the collapse of the very notion of well-being. On Aristotle’s view, if you are my friend, then my well-being is closely bound up with yours. It might be tempting, then, to say that ‘your’ well-being is ‘part’ of mine, in which case the distinction between what is good for me and what is good for others has broken down. But this temptation should be resisted. Your well-being concerns how well your life goes for you, and we can allow that my well-being depends on yours without introducing the confusing notion that my well-being is constituted by yours. There are signs in Aristotelian thought of an expansion of the subject or owner of well-being. A friend is ‘another self’, so that what benefits my friend benefits me. But this should be taken either as a metaphorical expression of the dependence claim, or as an identity claim which does not threaten the notion of well-being: if you really are the same person as I am, then of course what is good for you will be what is good for me, since there is no longer any metaphysically significant distinction between you and me.

Well-being is a kind of value, sometimes called ‘prudential value’, to be distinguished from, for example,

aesthetic value or moral value. What marks it out is the notion of 'good for'. The serenity of a Vermeer painting, for example, is a kind of goodness, but it is not 'good for' the painting. It may be good for us to contemplate such serenity, but contemplating serenity is not the same as the serenity itself. Likewise, my giving money to a development charity may have moral value, that is, be morally good. And the effects of my donation may be good for others. But it remains an open question whether my being morally good is good for me; and, if it is, its being good for me is still conceptually distinct from its being morally good.

2. Moore's Challenge

There is something mysterious about the notion of 'good for'. Consider a possible world that contains only a single item: a stunning Vermeer painting. Leave aside any doubts you might have about whether paintings can be good in a world without viewers, and accept for the sake of argument that this painting has aesthetic value in that world. Now it seems intuitively plausible to claim that the value of this world is constituted solely by the aesthetic value of the painting. But now consider a world which contains one invididual living a life that is good for them. How are to describe the relationship between the value of this world, and the value of the life lived in it for the individual? Are we to say that the world has a value at all? How can it, if the only value it contains is 'good for' as opposed to just 'good'? And yet we surely do want to say that this world is better ('more good') than some other empty world. Well, should we say that the world is good, and is so because of the good it contains 'for' the individual? This fails to capture the idea that there is in fact nothing of value in this world than what is good for the individual.

Thoughts such as these led G.E. Moore to object to the very idea of 'good for' (Moore 1903, pp. 98-9). Moore argued that the idea of 'my own good', which he saw as equivalent to what is 'good for me', makes no sense. When I speak of, say, pleasure as what is good for me, he claimed, I can mean only either that the pleasure I get is good, or that my getting it is good. Nothing is added by saying that the pleasure constitutes my good, or is good for me.

But the distinctions I drew between different categories of value above show that Moore's analysis of my claim that my own good consists in pleasure, is too narrow. Indeed Moore's argument rests on the very assumption that it seeks to prove: that only the notion of 'good' is necessary to make all the evaluative judgements we might wish to make. The claim that it is good that I get pleasure is, logically speaking, equivalent to the claim that the world containing the single Vermeer is good. It is, so to speak, 'impersonal', and leaves out of account the special feature of the value of well-being: that it is good for individuals.

Indeed, one way to respond both to Moore's challenge, and to the puzzles above, is to try, when appropriate, to do without the notion of 'good' and make do with 'good for', alongside the separate and non-evaluative notion of reasons for action. Thus, the world containing the single individual with a life worth living, might be said to contain nothing good *per se*, but a life that is good for that individual. And this fact may give us a reason to bring about such a world, given the opportunity.

3. Scanlon's Challenge

Moore's book was published in Cambridge, England, at the beginning of the twentieth century. At the end of the same century, a book was published in Cambridge, Mass., which also posed some serious challenges to the notion of well-being: *What Do We Owe to Each Other?*, by T.M. Scanlon.

Moore's ultimate aim in criticizing the idea of 'goodness for' was to attack egoism. Likewise, Scanlon has an ulterior motive in objecting to the notion of well-being -- to attack so-called 'telelogical' or end-based theories of ethics, in particular, utilitarianism, which in its standard form requires us to maximize well-being. But in both cases the critiques stand independently.

One immediately odd aspect of Scanlon's position that 'well-being' is an otiose notion in ethics is that he himself seems to have a view on what well-being is. It involves, he believes, among other things, success in one's rational aims, and personal relations. But Scanlon claims that his view is not a 'theory of well-being', since a theory must explain what unifies these different elements, and how they are to be compared. And, he adds, no such theory is ever likely to be available, since such matters depend so much on context.

Scanlon does, however, implicitly make a claim about what unites these values: they are all constituents of well-being, as opposed to other kinds of value, such as aesthetic or moral. Nor is it clear why Scanlon's view of well-being could not be developed so as to assist in making real-life choices between different values in one's own life.

Scanlon suggests that we often make claims about what is good in our lives without referring to the notion of well-being, and indeed that it would often be odd to do so. For example, I might say, 'I listen to Alison Krauss's music because I enjoy it', and that will be sufficient. I do not need to go on to say, 'And enjoyment adds to my well-being'.

But this latter claim sounds peculiar only because we already *know* that enjoyment makes a person's life better for them. And in some circumstances such a claim would anyway not be odd: consider an argument with someone who claims that aesthetic experience is worthless, or with an ascetic. Further, people do use the notion of well-being in practical thinking. For example, if I am given the opportunity to achieve something significant, which will involve considerable discomfort over several years, I may consider whether, from the point of view of my own well-being, the project is worth pursuing.

Scanlon argues also that the notion of well-being, if it is to be philosophically acceptable, ought to provide a 'sphere of compensation' -- a context in which it makes sense to say, for example, that I am losing one good in my life for the sake of gain over my life as a whole. And, he claims, there is no such sphere. For Scanlon, giving up present comfort for the sake of future health 'feels like a sacrifice'.

But this does not chime with my own experience. When I donate blood, this feels to me like a sacrifice. But when I visit the dentist, it feels to me just as if I am weighing up present pains against potential future

pains. And we can weigh up different components of well-being against one another. Consider a case in which you are offered a highly paid job, but many miles away from your friends and family.

Scanlon denies that we need an account of well-being to understand benevolence, since we do not have a general duty of benevolence, but merely duties to benefit others in specific ways, such as to relieve their pain. But, from the philosophical perspective, it may be quite useful to use the heading of ‘benevolence’ in order to group such duties. And, again, comparisons may be important: if I have several *pro tanto* duties of benevolence, not all of which can be fulfilled, I shall have to weigh up the various benefits I can provide against one another. And here the notion of well-being will again come into play.

Further, if morality includes so-called ’imperfect’ duties to benefit others, that is, duties that allow the agent some discretion as to when and how to assist, the lack of any overarching conception of well-being is likely to make the fulfillment of such duties problematic.

4. Theories of Well-being

4.1 Hedonism

On one view, human beings always act in pursuit of what they think will give them the greatest balance of pleasure over pain. This is ‘psychological hedonism’, and will not be my concern here. Rather, I intend to discuss ‘evaluative hedonism’ or ‘prudential hedonism’, according to which well-being consists in the greatest balance of pleasure over pain.

This view was first, and perhaps most famously, expressed by Socrates and Protagoras in the Platonic dialogue, *Protagoras* (Plato 1976 [C4 BCE]: 351b-c). Jeremy Bentham, perhaps the most well-known of the more recent hedonists, begins his *Introduction to the Principles of Morals and Legislation* thus: ‘Nature has placed mankind under the governance of two sovereign masters, *pain* and *pleasure*. It is for them alone to point out what we ought to do’.

In answer to the question, ‘What does well-being consist in?’, then, the hedonist will answer, ‘The greatest balance of pleasure over pain’. We might call this *substantive hedonism*. A complete hedonist position will involve also *formal hedonism*, which consists in an answer to the following question: ‘What *makes* pleasure good, and pain bad?’, the answer being, ‘The pleasantness of pleasure, and the painfulness of pain’. Consider a substantive hedonist who believed that what makes pleasure good for us is that it fulfills our nature. This theorist is not a formal hedonist.

Hedonism -- as is demonstrated by its ancient roots -- has long seemed an obviously plausible view. Well-being, what is good *for* me, might be thought to be naturally linked to what seems good *to* me, and pleasure does, to most people, seem good. And how could anything else benefit me if I did not enjoy it?

The simplest form of hedonism is Bentham’s, according to which the more pleasantness one can pack

into one's life, the better it will be, and the more painfulness one encounters, the worse it will be. How do we measure the value of the two experiences? The two central aspects of the respective experiences, according to Bentham, are their duration, and their intensity.

Bentham tended to think of pleasure and pain as a kind of sensation, as the notion of intensity might suggest. One problem with this kind of hedonism is that there does not appear to be a single common strand of pleasantness running through all the different experiences people enjoy, such as eating hamburgers, reading Shakespeare, or playing waterpolo. Rather, it seems, there are certain experiences we want to continue, and we might be prepared to call these -- for philosophical purposes -- pleasures (even though some of them, such as diving in a very deep and narrow cave, for example, would not normally be described as pleasurable).

But simple hedonism could survive this objection merely by incorporating whatever view of pleasure was thought to be plausible. A more serious objection is to the evaluative stance of hedonism itself. Thomas Carlyle, for example, described the hedonistic component of utilitarianism as the 'philosophy of swine', the point being that simple hedonism places all pleasures on a par, whether they be the lowest animal pleasures of sex or the highest of aesthetic appreciation. One might make this point with a thought experiment. Imagine that you are given the choice of living a very fulfilling human life, or that of a barely sentient oyster, which experiences some very low-level pleasure. Imagine also that the life of the oyster can be as long as you like, whereas the human life will be of eighty years only. If Bentham were right, there would have to be a length of oyster life such that you would choose it in preference to the human. And yet many say that they would choose the human life in preference to an oyster life of any length.

Now this is not a knockdown argument against simple hedonism. Indeed some people are ready to accept that at some length or other the oyster life becomes preferable. But there is an alternative to simple hedonism, outlined famously by J.S. Mill, using his distinction between 'higher' and 'lower' pleasures (1998 [1863], ch. 2). Mill added a third property to the two determinants of value identified by Bentham, duration and intensity. To distinguish it from these two 'quantitative' properties, Mill called his third property 'quality'. The claim is that some pleasures, by their very nature, are more valuable than others. For example, the pleasure of reading Shakespeare, by its very nature, is more valuable than any amount of basic animal pleasure. And we can see this, Mill suggests, if we note that those who have experienced both types, and are 'competent judges', will make their choices on this basis.

A long-standing objection to Mill's move here has been to claim that his position can no longer be described as formally hedonist. If higher pleasures are higher because of their nature, that aspect of their nature cannot be pleasantness, since that could be determined by duration and intensity alone. And Mill anyway speaks of properties such as 'nobility' as adding to the value of a pleasure. Now it has to be admitted that Mill is sailing close to the wind here. But there is logical space for a hedonist position which allows properties such as nobility to determine pleasantness, and insists that only pleasantness determines value. But one might well wonder how nobility could affect pleasantness, and why Mill did not just come out with the idea that nobility is itself a good-making property.

But there is a yet more weighty objection to hedonism of any kind: the so-called 'experience machine'.

Imagine that I have a machine that I could plug you into for the rest of your life. This machine would give you experiences of whatever kind you thought most valuable or enjoyable -- writing a great novel, bringing about world peace, attending an early Rolling Stones' gig. You would not know you were on the machine, and there is no worry about its breaking down or whatever. Would you plug in? Would it be wise, from the point of your own well-being, to do so? Robert Nozick thinks it would be a big mistake to plug in: 'We want to do certain things… we want to be a certain way… plugging into an experience machine limits us to a man-made reality' (Nozick 1974, p. 43).

One can make the machine sound more palatable, by allowing that genuine choices can be made on it, that those plugged in have access to a common 'virtual world' shared by other machine-users, a world in which 'ordinary' communication is possible, and so on. But this will not be enough for many anti-hedonists. A further line of response begins from so-called 'externalism' in the philosophy of mind, according to which the content of mental states is determined by facts external to the experiencer of those states. Thus, the experience of *really* writing a great novel is quite different from that of *apparently* writing a great novel, even though 'from the inside' they may be indistinguishable. But this is once again sailing close to the wind. If the world can affect the very content of my experience without my being in a position to be aware of it, why should it not affect the value of my experience?

The strongest tack for hedonists to take is to accept the apparent force of the experience machine objection, but to insist that it rests on 'common sense' intuitions, the place in our lives of which may itself be justified by hedonism. This is to adopt a strategy similar to that developed by 'two-level utilitarians' in response to alleged counter-examples based on common-sense morality. The hedonist will point out the so-called 'paradox of hedonism', that pleasure is most effectively pursued indirectly. If I consciously try to maximize my own pleasure, I will be unable to immerse myself in those activities, such as reading or playing games, which do give pleasure. And if we believe that those activities are valuable independently of the pleasure we gain from engaging in them, then we shall probably gain more pleasure overall.

These kinds of stand-off in moral philosophy are unfortunate, but should not be brushed aside. They raise questions concerning the epistemology of ethics, and the source and epistemic status of our deepest ethical beliefs, which we are further from answering than many would like to think. Certainly the current trend of quickly dismissing hedonism on the basis of a quick run-through of the experience machine objection is not methodologically sound.

4.2 Desire Theories

The experience machine is one motivation for the adoption of a desire theory. When you are on the machine, many of your central desires are likely to remain unfilled. Take your desire to write a great novel. You may believe that this is what you are doing, but in fact it is just a hallucination. And what you want, the argument goes, is to write a great novel, not the experience of writing a great novel.

Historically, however, the reason for the current dominance of desire theories lies in the emergence of welfare economics. Pleasure and pain are inside people's heads, and also hard to measure -- especially

when we have to start weighing different people's experiences against one another. So economists began to see people's well-being as consisting in the satisfaction of preferences or desires, the content of which could be revealed by their possessors. This made possible the ranking of preferences, the development of 'utility functions' for individuals, and methods for assessing the value of preference-satisfaction (using, for example, money as a standard).

The simplest version of a desire theory one might call the *present desire* theory, according to which someone is made better off to the extent that their current desires are fulfilled. This theory does succeed in avoiding the experience machine objection. But it has serious problems of its own. Consider the case of the *angry adolescent*. This boy's mother tells him he cannot attend a certain nightclub, so the boy holds a gun to his own head, wanting to pull the trigger and retaliate against his mother. Recall that the scope of theories of well-being should be the whole of a life. It is implausible that the boy will make his life go as well as possible by pulling the trigger. We might perhaps interpret the simple desire theory as a theory of well-being-at-at-a-particular-time. But even then it seems unsatisfactory. From whatever perspective, the boy would be better off if he put the gun down.

We should move, then, to a *comprehensive desire* theory, according to which what matters to a person's well-being is the overall level of desire-satisfaction in their life as a whole. A *summative* version of this theory suggests, straightforwardly enough, that the more desire-fulfilment in a life the better. But it runs into Derek Parfit's case of *addiction* (1984, p. 497). Imagine that you can start taking a highly addictive drug, which will cause a very strong desire in you for the drug every morning. Taking the drug will give you no pleasure; but not taking it will cause you quite severe suffering. There will be no problem with the availability of the drug, and it will cost you nothing. But what reason do you have to take it?

A *global* version of the comprehensive theory ranks desires, so that desires about the shape and content of one's life as a whole are given some priority. So, if I prefer not to become a drug addict, that will explain why it is better for me not to take Parfit's drug. But now consider the case of the *orphan monk*. This young man began training to be a monk at the earliest age, and has lived a very sheltered life. He is now offered three choices: he can remain as a monk, or become either a cook or a gardener outside the monastery, at a grange. He has no conception of the latter alternatives, so chooses to remain a monk. But surely it might be possible that he would have a better life were he to live outside?

So we now have to moved to an *informed desire* version of the comprehensive theory. According to the informed desire account, the best life is the one I would desire if I were fully informed about all the (non-evaluative) facts. But now consider a case suggested by John Rawls: the *grass-counter*. Imagine a brilliant Harvard mathematician, fully informed about the options available to her, who develops an overriding desire to count the blades of grass on the lawns of Harvard. Like the experience machine case, this case is another example of philosophical 'bedrock'. Some will believe that, if she really is informed, and not suffering from some neurosis, then the life of grass-counting will be the best for her.

But it does seem that all these problem cases for desire theories are symptoms of a more general difficulty. Recall again the distinction between substantive and formal theories of well-being. The former state the constituents of well-being (such as pleasure), while the latter state what makes these things good

for people (pleasantness, for example). Substantively, a desire theorist and a hedonist may agree on what makes life good for people: pleasurable experiences. But formally they will differ: the hedonist will refer to pleasantness as the good-maker, while the desire theorist must refer to desire-satisfaction. (It is worth pointing out here that if one characterizes pleasure as an experience the subject wants to continue, the distinction between hedonism and desire theories becomes quite hard to pin down.)

The idea that desire-satisfaction is a 'good-making property' is somewhat odd. As Aristotle says (1984 [C4 BCE], *Metaphysics* 1072a, tr. Ross): 'desire is consequent on opinion rather than opinion on desire'. In other words, we desire things, such as writing a great novel, because we think those things are independently good; we do not think they are good because they will satisfy our desire for them.

4.3 Objective List Theories

The threefold distinction I am using between different theories of well-being has become standard in contemporary ethics. There are problems with it, however, as with many classifications, since it can blind one to other ways of characterizing views. Objective list theories are usually understood as theories which list items constituting well-being that consist neither merely in pleasurable experience nor in desire-satisfaction. Such items might include, for example, knowledge or friendship. But it is worth remembering, for example, that hedonism might be seen as one kind of 'list' theory, and all list theories might then be opposed to desire theories as a whole.

What should go on the list? It is important that every good should be included. As Aristotle put it: 'We take what is self-sufficient to be that which on its own makes life worthy of choice and lacking in nothing. We think happiness to be such, and indeed the thing most of all worth choosing, not counted as just one thing among others' (2000 [C4 BCE], *Nicomachean Ethics* 1197b, tr. Crisp). In other words, if you claim that well-being consists only in friendship and pleasure, I can show your list to be unsatisfactory if I can demonstrate that enjoyment or pleasure is also something that makes people better off.

What is the 'good-maker', according to objective list theorists? This depends on the theory. One, influenced by Aristotle and recently developed by Thomas Hurka (1993), is *perfectionism*, according to which what makes things consituents of well-being is their perfecting human nature. If it is part of human nature to acquire knowledge, for example, then a perfectionist should claim that knowledge is a constituent of well-being. But there is nothing to prevent an objective list theorist's claiming that all that the items on her list have in common is that each, in its own way, advances well-being.

How do we decide what goes on the list? All we can work on is the deliverance of reflective judgement -- intuition, if you like. But one should not conclude from this that objective list theorists are, because they are intuitionist, less satisfactory than the other two theories. For those theories too can be based only on reflective judgement. Nor should one think that intuitionism rules out argument. Argument is one way to bring people to see the truth. Further, we should remember that intuitions can be mistaken. Indeed, as suggested above, this is the strongest line of defence available to hedonists: to attempt to undermine the

evidential weight of many of our natural beliefs about what is good for people.

One common objection to objective list theories is that they are élitist, since they appear to be claiming that certain things are good for people, even if those people will not enjoy them, and do not even want them. One strategy here might be to adopt a 'hybrid' account, according to which certain goods do benefit people independently of pleasure and desire-satisfaction, but only when they do in fact bring pleasure and/or satisfy desires. Another would be to bite the bullet, and point out that a theory could be both élitist and true.

It is also worth pointing out that objective list theories need not involve any kind of objectionable authoritarianism or perfectionism. First, one might wish to include autonomy on one's list, claiming that the informed and reflective living of one's own life for oneself itself constitutes a good. Secondly, and perhaps more significantly, one might note that any theory of well-being in itself has no direct moral implications. There is nothing logically to prevent one's holding a highly élitist conception of well-being alongside a strict liberal view that forbade paternalistic interference of any kind with a person's own life (indeed, on some interpretations, J.S. Mill's position is close to this).

One not implausible view, if desire theories are indeed mistaken in their reversal of the relation between desire and what is good, is that the debate is really between hedonism and objective list theories. And, as suggested above, what is most at stake here is the issue of the epistemic adequacy of our beliefs about well-being. The best way to resolve this matter would consist, in large part at least, in returning once again to the experience machine objection, and seeking to discover whether that objection really stands.

5. Well-being and Morality

5.1 Welfarism

Well-being obviously plays a central role in any moral theory. A theory which said that it just does not matter would be given no credence at all. Indeed, it is very tempting to think that well-being, in some ultimate sense, is all that can matter morally. Consider, for example, Joseph Raz's 'humanistic principle': 'the explanation and justification of the goodness or badness of anything derives ultimately from its contribution, actual or possible, to human life and its quality' (Raz 1986, p. 194). If we expand this principle to cover non-human well-being, it might be read as claiming that, ultimately speaking, the justificatory force of any moral reason rests on well-being. This view is *welfarism*.

Act-utilitarians, who believe that the right action is that which maximizes well-being overall, may attempt to use the intuitive plausibility of welfarism to support their position, arguing that any deviation from the maximization of well-being must be grounded on something distinct from well-being, such as equality or rights. But those defending equality may argue that egalitarians are concerned to give priority to those who are worse off, and that we do see here a link with concern for well-being. Likewise, those concerned with rights may note that rights are to certain goods, such as freedom, or the absence of 'bads', such as

suffering (in the case of the right not to be tortured, for example). In other words, the interpretation of welfarism is itself a matter of dispute. But, however it is understood, it does seem that welfarism poses a problem for those who believe that morality can require actions which benefit no one, and harm some, such as, for example, punishments intended to give individuals what they deserve.

5.2 Well-being and Virtue

Ancient ethics was, in a sense, more concerned with well-being than a good deal of modern ethics, the central question for many ancient moral philosophers being, ‘Which life is best for one?’. The rationality of egoism -- the view that my strongest reason is always to advance my own well-being -- was largely assumed. This posed a problem. Morality is naturally thought to concern the interests of others. So if egoism is correct, what reason do I have to be moral?

One obvious strategy to adopt in defence of morality is to claim that a person’s well-being is in some sense constituted by their virtue, or the exercise of virtue, and this strategy was adopted in subtly different ways by the three greatest ancient philosophers, Socrates, Plato, and Aristotle. At one point in his writings, Plato appears to allow for the rationality of moral self-sacrifice: the philosophers in his famous ‘cave’ analogy in the *Republic* (519-20) are required by morality to desist from contemplation of the sun outside the cave, and to descend once again into the cave to govern their fellow citizens. In the voluminous works of Aristotle, however, there is no recommendation of sacrifice. Aristotle believed that he could defend the virtuous choice as always being in the interest of the individual.

His primary argument is his notorious ‘function argument’, according to which the good for some being is to be identified through attention to its ‘function’ or characteristic activity. The characteristic activity of human beings is to exercise reason, and the good will lie in exercising reason well -- that is, in accordance with the virtues. This argument, which is stated by Aristotle very briefly and relies on assumptions from elsewhere in his philosophy and indeed that of Plato, appears to conflate the two ideas of what is good for a person, and what is morally good. I may agree that a ‘good’ example of humanity will be virtuous, but deny that this person is doing what is best for them. Rather, I may insist, reason requires one to advance one’s own good, and this good consists in, for example, pleasure, power, or honour. But much of Aristotle’s *Nicomachean Ethics* is taken up with portraits of the life of the virtuous and the vicious, which supply independent support for the claim that well-being is constituted by virtue. In particular, it is worth noting the emphasis placed by Aristotle on the value to a person of ‘nobility’ (*to kalon*), a quasi-aesthetic value which those sensitive to such qualities might not implausibly see as a constituent of well-being of more worth than any other. In this respect, the good of virtue is, in the Kantian sense, ‘unconditional’. Yet, for Aristotle, virtue or the ‘good will’ is not only morally good, but good for the individual.

Bibliography

Two significant recent works are Griffin (1986), which presents an objective list theory, and Sumner (1996), which rejects many current options and advocates a theory of well-being based on the idea of ‘life-satisfaction’. A collection of useful essays is Nussbaum and Sen (1993).

Causation in the law

The basic questions dealt with in this entry are: (i) whether and to what extent causation in legal contexts differs from causation outside the law, for example in science or everyday life, and (ii) what are the appropriate criteria in law for deciding whether one action or event has caused another, (generally harmful) event. The importance of these questions is that responsibility in law very often depends on showing that a specific action or event or state of affairs has caused specific harm or loss to another. Are the criteria adopted in deciding these causal issues both objective and properly attuned to the function of fixing responsibility?

The entry covers the nature and functions of causation, the relation between causation and legal responsibility, and the criteria for the existence of causal connection in law. The last topic is treated in two parts: what are causally relevant conditions (‘causes-in-fact‘) and what are the grounds for limiting responsibility (the ‘proximate cause’ requirement).

1. Nature and Functions of Causation

Law is concerned with the application of causal ideas, embodied in the language of statutes and decisions, to particular situations. This involves, first, a conception of what a cause is outside the law. To this a variety of answers empirical (Hume) and metaphysical (Kant) have been given and each has its contemporary supporters.

Secondly, a theory is required of how causal notions should function in different contexts. In the context of application the notion of cause is a multi-purpose tool. One function, perhaps fundamental, is forward-looking: that of specifying what will happen and by what stages if certain conditions are present together. This use of cause serves to provide recipes and make predictions. It also yields the idea of a causal process. Another function is backward-looking and explanatory: that of showing which earlier conditions

best account for some later event or state of affairs. A third function is attributive: that of fixing the extent of responsibility of agents for the outcomes that follow on their agency or intervention in the world.

For the first of these purposes the emphasis falls on a cause as consisting of the whole complex of conditions required if a certain outcome is to follow (J.S. Mill). Even when applied to a specific situation this involves considering what generally happens when certain conditions are present. In the second, explanatory, context the focus is on selecting from the whole complex the particular condition or conditions that best explain a given outcome. The aim can be either to explain a class of events or a particular event. In the third, attributive, context the aim is again selective, but from a different point of view. It is to attribute responsibility to an agent for those outcomes that his, her or its agency serves to explain and that can therefore plausibly be treated as part of the agency's impact on the world. Here the purpose is to settle the extent of responsibility that attaches to a particular human action or other event or state of affairs. This responsibility is then attributed to an agent or, metaphorically, to the other event or state of affairs in question (e.g. outbreak of war, high unemployment).

In law the second and third of these functions of the notion of cause are prominent, often in combination. Many legal inquiries are concerned to explain how some event or state of affairs came about, especially an untoward event such as death or a state of affairs such as insolvency. But in law the third function is particularly salient and controversial. Whether someone is liable to punishment or to pay compensation or is entitled to claim compensation often depends on showing whether the person potentially liable or entitled has caused harm of a sort that the law seeks to avoid. For example, all systems of law hold that a person can be guilty of homicide only if he or she has caused another's death. All systems treat it as a more serious offence to cause death than to attempt to do so. It is a civil wrong to cause injury to another by negligence in driving a vehicle, but the claim is barred or reduced if the negligent conduct of the person injured is also a cause of the injury. An insurer is required to pay for losses caused by an event of the type defined in the insurance policy, such as fire or flooding, but not if the cause of the loss is something else.

The attribution of responsibility on causal grounds is not confined to law. Historians and moralists, for example, assess the responsibility of agents for the outcomes, political, social, economic or military of what they did or failed to do. Unlike lawyers, they are concerned with responsibility for good as well as bad outcomes. But whereas historians may aim to assess the outcome of an agent's conduct over a period or even a lifetime, lawyers focus on the harmful outcomes of particular actions. These uses of causation by historians, moralists and lawyers raise the question, adumbrated by Collingwood, of whether the attribution of responsibility requires a different conception of cause from that employed for prediction or explanation. In the legal theory of causation this problem is of central importance.

2. Causation and Legal Responsibility

When rules of law attributing responsibility for harm caused are formulated in statutes, regulations and judicial decisions, the word 'cause' is often used. The notion that causal connection between agency and

harm must be established is however often implied even when the word is not used. This is true, for example, of the use of verbs such as ‘damage’, which imply a causal relation between an agency and the harm done. In legal contexts the possible range of agency is not confined to human conduct, but may extend to damage done by the agency of juristic persons, animals, inanimate objects such as motor vehicles and inanimate forces such as fire. In all these instances the use of the notion of cause is central to the legal inquiry, since to establish responsibility it must be shown that the harm was done or brought about by the agency that the law treats as a potential basis for the existence or extent of liability.

The relationship between causing harm and legal responsibility is however complex. The complexities concern the *incidence* of responsibility, the *grounds* of responsibility, the *items* between which causal connection must be demonstrated, and the variety of *relationships* that can in some sense be regarded as causal. So far as the *incidence* of responsibility is concerned, while in law the relevant causes may be human or animal behaviour or natural events or processes, legal responsibility attaches in modern law only to natural persons (human beings) and juristic persons such as states, corporations and other institutions to which personality is ascribed in law.

As regards the *grounds* of responsibility it is important to grasp that for a person to cause harm or loss to another (the term ‘harm’ will be used for short) is in law neither a necessary nor a sufficient condition of being legally responsible for the harm. It is not a necessary condition for two reasons. First, in legal contexts people are often made responsible for harm caused by other persons (e.g. the vicarious liability of employers for employees), animals (e.g. the bite of a dangerous dog), inanimate objects (e.g. the collapse of buildings, the impact of vehicles) or processes (e.g. fire, subsidence). In these instances the ground of responsibility is, from the point of view of the person held responsible, not that he, she or it has caused harm but that they bear the risk that some other person, animal, thing or process may cause harm. The risk may be voluntarily assumed, as in insurance contracts, or may be imposed by law, as in the case of employers’ liability for wrongs committed by employees in the course of their employment. Much law is indeed concerned with the distribution of social risks. The responsibility of the person who bears the risk may be additional or alternative to the responsibility of the person (if any) who wrongfully caused the harm in question. Thus, if an employer is responsible for harm caused by his or her employee to another person the employee may or may not also be legally responsible for that harm. In law the main grounds of responsibility for harm are therefore (i) an agent’s personal responsibility for causing harm and (ii) a person’s responsibility arising from the fact that he, she or it bears the risk of having to answer in legal proceedings for the harm in question.

A second reason why causing harm is not a necessary condition of legal responsibility is that there are many contexts in which a person is civilly or criminally responsible irrespective of whether any harm has been caused by their conduct or that of an agency for which they are responsible. Thus, in Anglo-American law those who trespass on another’s land or who break a contract may be civilly liable and those who unlawfully possess firearms criminally liable though no tangible harm is thereby caused to anyone. Both inside and outside the law many actions are regarded as wrongful whether or not they cause tangible harm. Moreover the imposition of penalties in civil law and of punishments in criminal law need not bear any relation to the harm (if any) caused by the conduct for which the penalty or punishment is imposed.

To cause harm to another is also not a sufficient condition of legal responsibility, even in the eyes of those, such as the early Epstein, who would in general favour making agents strictly liable for the harm they cause. For a person to be legally responsible for causing harm to another requires, apart from a number of conditions relating to jurisdiction, procedure and proof, that the conduct should be of the sort that the law designates as unlawful (e.g. negligent driving) or as a potential source of liability (e.g. keeping a dangerous animal). It also requires that the purpose of the law should encompass harm of the sort for which a remedy is sought. Thus, in some contexts only physical, not economic or psychological harm grounds a legal remedy. Moreover considerations of morality must not rule out liability, as they well might if, for example, a burglar were to claim compensation for an injury suffered while breaking a window in order to enter the victim's house.

There is also a complication concerning the *items* between which causal connection must in law be shown to exist. The inquiries with which law is concerned relate to particular events. Did one action, event, process or state of affairs (event for short) cause another? The link that must be established in legal proceedings between events is of a special type. A person's conduct or a natural event or process can always be described in a number of different ways, but only certain descriptions of an alleged cause are crucial in legal proceedings. For example, if a claim for damages is brought against a motorist for causing injury to the claimant by driving negligently, only that description of his or her manner of driving that amounts to negligence is capable of constituting a relevant cause. Hence 'On 5 March at 5 p.m. Smith drove at sixty miles an hour in a built-up area' may be relevant while ';Smith drove a Mercedes' may not be, though both correctly describe Smith's act of driving a car on the occasion in question. In a legal context, therefore, the link to be established must be framed in terms of a link between particular aspects of events. The claimant in a civil action will typically argue, for example, that the fact that Smith drove at sixty miles an hour in a built-up area on such-and-such an occasion caused the collision that in turn caused the victim to suffer a broken leg. Though it is controversial whether causal connection is to be conceived as a relation between events or facts (Davidson), in law both are relevant. The events in issue must be identified from the point of view of the time, place and persons involved, but the aspect of the events between which a causal link must be shown has to be specified in such a way as to show that it falls within the relevant legal categories, such as (in the example given above) negligence and physical injury.

The relationship between causing harm and legal responsibility is also complex because of the great *variety of relationships* between agency and harm that can be regarded as in some sense causal, or analogous to a causal relationship. An omission to prevent harm when the person concerned has a legal duty to prevent it can ground legal responsibility but would ordinarily be described as 'not preventing' rather than causing the harm. Again, legal responsibility is often imposed, in the context of interpersonal relationships, on those who influence others by advising, encouraging, helping, permitting, coercing, deceiving, misinforming or providing opportunities to others that motivate or enable them to act in a way that is harmful to themselves or to others. In some cases (coercion, deceit) the persons held responsible would naturally be said to have caused the persons influenced to act as they did, while in others they would not, though the weaker interpersonal relationship is in some respects analogous to more plainly causal relationships. Failing to help or provide opportunities to others by advising, warning, informing or

rescuing them or supplying them with agreed goods and services are other grounds of responsibility for negative agency that, again, are at least analogous to causal relationships. The existence of this wide spectrum of causal or near-causal grounds of responsibility recognised in law and morality raises the question whether any uniform theory of causation is capable of accounting for all of them.

3. Criteria for the Existence of Causal Connection in Law

The theories concerning the criteria for the existence of causal connection in law fall into two classes. Some focus on the type of condition that the alleged cause must constitute in relation to the alleged consequence. Others are concerned with a specific feature that the cause must possess in relation to the consequence in order that causal connection may be made out. The first class of theory concerns the identification of the causally relevant conditions of an outcome, or, in the language of causal minimalists, ‘cause-in-fact’. Must the cause be a necessary condition, a sufficient condition or a necessary member of a set of conditions that are together sufficient for the outcome? In law these terms, much discussed in the philosophical literature, are interpreted as meaning ‘necessary or sufficient in the particular circumstances in issue’. The inquiry will be, for example, into what was a necessary or sufficient to cause a particular persons’ death, not what are in general the necessary or sufficient conditions of death.

The second type of theory concerns the criteria for determining the limits of legal responsibility for causing harm. Even supposing that the alleged cause constitutes the right sort of condition of the outcome (e.g. a necessary condition), responsibility cannot extend indefinitely. The failure of a doctor to prescribe an effective contraceptive cannot be held to be responsible for the death of the victim of a murder committed by the child conceived as a result of the doctor’s negligence. Some consequences are ‘too remote’. But what are the appropriate criteria of limitation?

In many legal contexts and in the view of many theorists a single criterion is called for. It should be remembered, however, that the search for a single criterion may be no more than a response to legal doctrine. This sometimes requires all the limiting factors to be brought under a single umbrella, such as ‘proximate cause’ or ‘adequate cause’ even though, underlying these phrases, there are a number of distinct reasons for imposing limits on the extent of responsibility. A number of expressions are used to describe the allegedly single limiting factor, in particular ‘proximate (adequate, direct, effective, operative, legal, responsible)’ cause in contrast with ‘remote, indirect or legally inoperative’ causes.

Some theorists (for example Leon Green and others since the 1920’s up to Wright and Stapleton today) hold that only the issue of causally relevant condition or cause-in-fact is genuinely causal. It alone raises questions to which an objective, scientifically valid, answer can be given (Becht and Miller). Even this has been questioned by Malone, who has pointed to the incorporation of normative considerations in the rules for proving cause-in-fact in civil law. The second type of theory concerns questions of responsibility that would in the view of these causal minimalists be better addressed directly rather than by asking whether on the facts a causal relation existed between agency and harm. One way of doing this

is to ask what would be the fairest way of distributing the relevant social risks. Another (Posner) would be to place responsibility, especially in civil law, on the person best placed to avoid the loss most cheaply. In practice legislators and judges have seldom abandoned the traditional terminology in discussing the second issue, but the proposal to do so has been repeatedly revived.

3.1 Causally relevant conditions: ‘Cause-in-fact’

What sort of condition must be attributed to an agency for its action or intervention (action for short) to count as causal? Opinion is divided between those to whom the action must in the circumstances be necessary to the outcome (a but-for condition), those to whom it must in the circumstances form a necessary part of a complex of conditions sufficient for the outcome (a NESS condition), and those who would describe the required connection in a more quantitative or scalar mode by requiring that the action be a ‘substantial factor in’ or ‘contribute to’ the outcome.

The but-for theory, endorsed by many legal and philosophical theorists including Mackie, has the heuristic advantage that a simple and often reliable way of ruling out the existence of causal connection between agency and harm is to ask whether the harm would in the circumstances have occurred in the absence of the agency. If the harm would have occurred in any event the agency is probably not its cause or one of its causes. If it would not have occurred in the absence of the agency the agency will be a causally relevant condition or, if one endorses causal minimalism, a cause-in-fact of the harm.

There are however cases in which the but-for test is difficult to reconcile with our intuitive judgements of responsibility. These concern two types of case in particular, those of over-determination and of joint determination. If two huntsmen independently but simultaneously shoot and kill a third person, or two contractors independently fail to deliver essential building supplies on time, it is intuitively clear that each should be held responsible for the death or building delay. Yet the but-for test seems to yield the conclusion that neither has caused the harm. Again, in interpersonal relationships it is often the case that advice etc. can be regarded as contributing to a person’s decision without its being shown that the person would not have acted as they did apart from the advice. Many reasons bear on the decisions we make. Sometimes it is not possible to be sure that in the absence of one of them the decision would have been different. We know only that to the person reaching the decision the reasons taken into account were jointly sufficient to induce him, her or it to decide as he or she did.

In reply it is argued (Mackie) that in these cases all the agencies that are singly or jointly sufficient for the outcome together constitute its cause. But in law this does not solve the problem because, unless the agents are acting in concert, the responsibility of each agency has to be independently established. This can be done either by an appeal to intuitive notions of responsibility or by recourse to an alternative ground of responsibility based on risk. On the alternative view an agency that provides an independently or jointly sufficient condition of harm bears the risk that that harm will eventuate even if it would in the circumstances have come about in any event.

Some of those who reject this approach (e.g. Hart and Honoré, Wright) have recourse to a theory based

on J.S.Mill's notion of a jointly sufficient set of conditions. The theory also draws on Mackie's idea, in the context of causal generalisations, of an INUS condition (insufficient but non-redundant part of an unnecessary but sufficient condition). They advocate the view that in a specific situation a causally relevant condition is a necessary element of a set of conditions jointly sufficient for the harmful outcome. For this Wright's term NESS condition (necessary element of a sufficient set) is currently used, a NESS condition being a specific instance of an INUS condition. NESS supporters therefore appeal to the idea that particular causal links are instances of generalisations about the way in which events are connected. They argue that in order to test whether an outcome would have occurred in the absence of the agency in question it is necessary to make a counterfactual calculation, which can only be done on the basis of such generalisations.

Those who reject the NESS theory either assert that singular causal judgments do not depend on generalisations or point to the fact that reliable generalisations of the sort presupposed by it are in practice virtually confined to inorganic physical processes. Organic processes, such as those involved in the development of disease, and, still more, in decision-making by human beings, do not conform to settled patterns. The NESS theory therefore has at most a narrow range of application.

Some of those who are impressed by what they see as the deficiencies of both the but-for and NESS theories prefer a more quantitative or scalar approach, according to which an agency can cause an outcome to a greater or less extent (Moore). They argue that an agency must be a 'substantial factor in' or 'contribute to' the harmful outcome in order to be legally a cause of it. This approach has a particular attraction when a number of processes (e.g. several fires or pollutants) merge to bring about harm. It enables distinctions to be made according to the extent of contribution of a particular process to the outcome. It also fits the rule that in most legal contexts an agency, in order to be responsible for the whole of the harm that ensues, need only be shown to be one of the causes of harm, not the sole cause. The criticism that can be made of this approach is that it presupposes an independent understanding of causes as necessary and/or sufficient conditions in relation to their consequences.

Difficult legal problems arise in certain cases of overdetermination, often termed those of 'overtaking causes' or 'causal preemption'. Suppose that a lethal dose of poison is given but the victim is fatally wounded before the poison takes effect. The pre-empting, not the pre-empted condition is taken to be the cause of the death. Which condition is taken to preempt the other is sometimes controversial but it is clear than in reaching a decision attention must be paid to the stages and processes by which the alleged causes lead to the harmful outcome.

The idea that responsibility should depend on the agent's having changed the course of events points in the direction of the but-for theory. The function of cause in relation to recipes and prediction points towards the NESS theory. The phenomenon of multiple causes, which have often to be weighed against one another, points to a quantitative theory. But whichever is favoured has to be applied in the light the law's commitment to vindicating rights and securing a fair distribution of risks.

3.2 'Proximate cause'

The theories about the specific qualities that an agency must possess in relation to the outcome in order to be its cause in law are in Anglo-American law often grouped under this rubric, though many other terms (e.g. adequate, direct, efficient, operative, legal, responsible) are also found in the literature. These limiting theories are invoked because if every causally relevant condition (cause-in-fact) is treated as grounding responsibility for the outcomes to which it is causally relevant the extent of legal responsibility will extend almost indefinitely. (This alarming scenario would however be subject to independent legal requirements as regards proof, type of damage and lapse of claims through the passage of time). The theories in question therefore embody reasons for limiting the extent of legal responsibility. The reasons adduced for limiting responsibility are however differently viewed by different theorists. Causal minimalists treat all these theories as non-causal, in the sense that they embody grounds of legal policy other than the policy of holding the agent responsible for the harm caused by their action or intervention. Others treat some of the suggested limiting factors as causal and others as non-causal. It is indeed not open to dispute that at least two non-causal factors limit the extent of legal responsibility. One is the scope and purpose of the rule of law in question. No rule is intended to give a remedy for every conceivable type of harm or loss. Another concerns the aspiration of the law to achieve results that are morally unobjectionable. This rules out certain claims that would be inequitable on the part of the claimant or unfair towards the agent. It needs to be stressed that the grounds for limiting responsibility will not necessarily be the same in every branch of the law. In particular, the greater the weight attached to considerations of risk distribution the more likely it is that different limits will be appropriate in, for example, criminal, civil and public law.

3.3 Allegedly causal grounds of limitation

Certain theorists reject causal minimalism, which involves a restricted notion of cause that is current in no extra-legal context. They propose grounds of limitation that reflect the causal judgements that would be made outside the law. They claim that these grounds have a basis in ordinary usage (Hart & Honoré) or in the metaphysics of causation (Moore). The chief grounds proposed are that responsibility is limited (i) when a later intervention of a certain type is a condition of the harmful outcome (ii) when the agency has not substantially increased the probability of the harmful outcome that in fact supervenes and (iii) when the causal link involves a series of steps and ultimately peters out, so that the outcome is too remotely connected with the alleged cause. They argue that in these cases the agency, though a causally relevant condition, did not cause the outcome.

The idea that responsibility is excluded when the harm in question was conditioned by a *later intervention* is conventionally expressed by saying that an intervening or superseding cause broke the causal link between agency and outcome. These ‘breaks’ are not conceived as physical discontinuities in the course of events. The metaphor derives rather from the fact that in an explanatory context a cause may be regarded as an intervention in the normal course of events. The most persuasive explanations of an outcome are those that point to a condition that is abnormal or unexpected in the context or to a deliberate action designed to bring the outcome about. If these criteria are then applied in attributive contexts, an agency will not be regarded as the cause of an outcome when that outcome is explained by a later abnormal action or conjunction of events or a deliberate intervention designed to bring it about. A

later event of this sort is contrasted with a state of affairs (e.g .victim’s thin skull) existing at the time of the alleged cause. The latter, however extraordinary, does not preclude the attribution of the outcome to which it contributes to the alleged cause. In practice this notion is widely applied in both civil and, as Kadish has shown, criminal law. The use of these criteria of intervention in legal systems is said to be derived from common sense and to be consistent with treating causal issues in law as questions of fact. It is also supported (Honoré) on the ground that to attribute only a limited range of outcomes, whether achievements or failures, to human agents fosters a sense of personal identity that would be lost if the attribution to agents was not limited in this way. If there were not such a limiting factor we should have to share our successes and failures with many other people of whom it could be said that but for their actions what we think of as ‘our’ distinctive successes and failures would not have occurred. For example the success of a student in an examination would be *equally* the achievement of all those (parent, teacher, doctor, grant-giver, girl/boy friend) who made it possible for the student to succeed. It would not be specially the student's.

The criticism of this notion of later intervention takes two forms. First, the criteria set out are too vague to govern decision in controversial cases. Suppose that a motorist negligently injures a pedestrian, who is then taken to hospital and wrongly treated for the injury. Instead of asking whether the mistaken treatment was so abnormal as not to be accounted a consequence of the motorist’s negligent driving it would, in the critics’ eyes, be better to ask whether the risk of medical mistreatment should be borne exclusively by the hospital authorities. Secondly, even if the criteria suggested for selecting certain conditions as causes are in place in explanatory inquiries they are not necessarily so in attributing responsibility. There is no good reason to transfer them from an explanatory to an attributive context. To do so in civil law may result in saddling a person guilty of momentary carelessness with massive losses (Waldron).

Another limiting notion that has some claim to be regarded as causal is that of *probability*. According to the adequate cause theory, put forward by the physiologist Von Kries in 1886, developed systematically by Träger and advocated in a contemporary form by Calabresi, an agency is a cause only if it significantly increases the objective probability of the outcome that in fact ensues. Objective probability is here contrasted with subjective foreseeability, but this probability must be relative to an assumed epistemic base. It is inevitably a matter of policy which base to choose, and whether to include information not known or not available to the agent when he or she or it acted. Responsibility is excluded in relation to an outcome the probability of which was not substantially increased by the agency in question. This theory, long orthodox in German civil law, but increasingly supplemented by policy-oriented criteria, is intuitively attractive when the agent wrongfully exposes someone to a risk of harm to which they would not otherwise be exposed. For example, the agent wrongfully obstructs a pathway so that the claimant is forced to take a more dangerous route along a canal, and falls into the canal, sustaining injury. The obstructer is then the adequate cause of the injury. But one who wrongfully delays a passenger who is as a result obliged to board a later airplane, which crashes, is not the adequate cause of the passenger’s death in the crash. At least on the basis of information available at the time, the probability of being killed in an air crash was not substantially increased by the delay.

There are however instances in which an agency substantially increases the probability of harm but the

harm that occurs would intuitively be attributed to a later intervention. Suppose, for example, that in the example given a passer-by deliberately threw the claimant into the canal. It would be natural to attribute any injury suffered by the claimant not to the obstruction of the pathway but to the act of the third person. This objection can be met by having recourse to the risk theory, a version of the probability theory with strong support in Anglo-American writing in both criminal and civil law (Keeton, Seavey, Glanville Williams). According to this theory responsibility for harmful outcomes is restricted to the type of harm the risk of which was increased by the agency's intervention. The harm must be 'within the risk'. But much then turns on how the agent's conduct and the risk are defined. Is the risk of falling into the canal different from the risk of being pushed into it?

As stated earlier, in law responsibility for harm can rest on risk allocation as well as on causation. The risk theory has merits that are independent of its claim to explain what it is for an agency to cause harm. It can be treated as illustrating a wider principle that responsibility for harm is confined to the type of harm envisaged by the purpose of the rule of law violated (Normzweck), a theory espoused in Germany (Von Cämmerer, J.G.Wolf). For example, if a rule requiring machinery to be fenced is designed to prevent harmful contact between the machinery and the bodies of workmen, a workman who suffers psychological harm from the noise made by the unfenced machine cannot ground a claim for compensation on the failure to fence. The fencing requirement was not designed to reduce noise, even though a proper barrier would have reduced the noise to such an extent as to avoid the psychological trauma.

The limitations set by the purposes of legal rules cannot be regarded as causal. They vary from one branch of the law and one legal system to another. It is true that sometimes the purpose of legal prohibition may be the simple one of imposing responsibility for the harm caused by a breach of that prohibition. In that case the limits set by causal and purposive criteria coincide. But even in such a case it is a matter of legal policy which types of harm are to be compensated or to lead to criminal liability. The purposive limits on responsibility have therefore either to be regarded as additional to those (later intervention, heightened probability) proposed by those who reject causal minimalism, or as replacing them. The latter view is consistent with causal minimalism.

Other proposed criteria of limitation are based on moral considerations. Theorists who regard fault as an essential condition of criminal or civil responsibility often argue that a person should not be liable for unintended and unforeseeable harm. There are problems about settling whether only the type of harm or the specific harm must be unforeseeable, and the moment at which foreseeability is to be judged. But foreseeability, though it bears some relation to probability, is clearly a non-causal criterion, and one that can apply only to human conduct, not to other alleged causes. Moreover some supporters of the risk theory argue that different criteria should govern the existence and extent of legal liability. Even if the foreseeability of harm is a condition of liability, sound principles of risk allocation place on the agent who is at fault in failing to foresee and take precautions against harm the risk that an unforeseeable extent of harm will result from his or her fault, provided that this is of the type that the rule of law in question seeks to prevent.

There is no reason to suppose that the law, when it engages in explanatory inquiries, adopts different

criteria of causation from those employed outside the law in the physical and social sciences and in everyday life. However, even here, requirements of proof may lead to a divergence, for example, between what would medically be treated as the cause of a disease and what counts in law as its cause. As regards attributive uses of cause, the fact that the law has to attend simultaneously both to the meaning of terms importing causal criteria and to the purposes of legal rules and their moral status makes the theory of causation a terrain of debate that is unlikely to yield solutions commanding general agreement (e.g. Stapleton, Wright 2001; Moore, forthcoming).

Spinoza's Psychology

In Part III of his *Ethics*, "On the Origin and Nature of the Affects," Spinoza addresses two of the most serious challenges facing his thoroughgoing naturalism. First, he attempts to show that human beings follow the order of nature. Human beings, on Spinoza's view, have causal natures similar in kind to other ordinary objects, other "finite modes" in the technical language of the *Ethics*, so they ought to be analyzed and understood in the same way as the rest of nature. Second, Spinoza attempts to show that moral concepts, such as the concepts of good and evil, virtue, and perfection, have a basis in human psychology. Just as human beings are no different from the rest of nature, so moral concepts are no different from other concepts. They must be wholly explicable under the same laws which explain the rest of nature. Spinoza's detailed account of the human affects--the actions and passions of the human mind--is crucial to both tasks. For his argument to succeed, the theory of the affects must be both a plausible account of human psychology and a plausible basis for ethics.

---

1. The Human Being as Part of Nature

In the Preface to Part III, Spinoza states his view that all things alike must be understood to follow from the laws of nature:

> The laws and rules of nature, according to which all things happen, and change from one form to another, are always and everywhere the same. So the way of understanding the nature of anything, of whatever kind, must also be the same, viz. through the universal laws of nature.

Many philosophers have treated the human mind as an exception to otherwise universal natural laws, as a thing which is capable of good and evil or as an uncaused cause of action for example. Spinoza though insists that human beings are not "outside nature." Any features or deeds of human beings that seem exceptional, then, must have for Spinoza some explanation in terms of natural laws. That is, if there is any sense at all in saying that something which happens to a particular human being is good or evil, that must be a sense in which any other finite mode might also be said to have benefitted or have been harmed; and, if there is any sense at all in calling a human being free, that must be a sense in which other things of different kinds might also be said to be free.

Spinoza's thesis (IIIp7) that the essence of any finite mode, including any human mind (IIIp9), is a striving (*conatus*) to persevere in being is an attempt to give an account of nature under which human beings with their apparent peculiarities are natural. Spinoza argues that all finite modes strive to persevere in being (IIIp6), and he uses an analysis of human striving to explain human good and evil and human freedom in terms that might apply to any finite modes. An action of a human mind (IIp48) or of anything other than God (Ip17c2), cannot be free, for Spinoza, in the sense of being the effect of a free cause. There is human freedom for Spinoza, however, in the sense of freedom from external interference: I am free in producing some effect (for example, in doing something) if that effect follows from my essence alone, or, in other words, if it is the effect of my striving alone. (For discussions of action and human freedom, see IIId2 and V Preface.) 'Good' and 'evil' are labels that describe natural properties in the sense that they describe changes that might occur in any particular things at all (although we reserve the labels for these changes when they occur in human beings). An increase in the power with which a mind strives is good, for Spinoza, and a decrease evil (see IIIp11s, IIIp39s and IV Preface). Because the striving thesis thus explains both human freedom and good and evil, it is of central importance to Spinoza's psychology and ethics. One might raise questions about the validity of Spinoza's argument to the doctrine, about its plausibility as an account of the nature of particular objects, or about its plausibility as an account of human nature. The subsections which follow address these issues in turn.

1.1 The Argument to the Striving Doctrine

Spinoza's argument to IIIp6 is uncharacteristically insulated from the rest of the *Ethics*. As Spinoza presents the argument at IIIp6d, it depends principally upon IIIp4, a proposition which Spinoza takes to be self-evident, and IIIp5 which derives from IIIp4 alone. The argument also involves, less directly, IP25C and its gloss at IP34.

> I Proposition 25 Corollary: Particular things are nothing but affections of God's attributes, or modes by which God's attributes are expressed in a certain and determinate way.

> I Proposition 34: God’s power is his essence itself.
>
> III Proposition 4: No thing can be destroyed except through an external cause.
>
> III Proposition 5: Things are of a contrary nature, i.e., cannot be in the same subject, insofar as one can destroy the other.
>
> Therefore, I Proposition 6: Each thing, as far as it can by its own power, strives to persevere in its being.

A thing’s essence may not be absolutely equivalent to its nature for Spinoza, since a thing such as a square circle has a nature but cannot exist (Ip11) and one might interpret Spinoza as holding that anything which has an essence might exist (IId2). Still, the two terms might be taken interchangeably here because Spinoza is only describing existents. If this assumption is correct, then perhaps Spinoza’s reasoning runs like this:

> Particular things, subjects, are expressions of power, since they are modes of God’s attributes (Ip25) and God’s attributes constitute God’s essence (ID4) and God’s essence is his power (Ip34). It is self-evident that nothing can be destroyed except through an external cause (IIIp4), so an apparent particular thing which is self-destructive is in fact at least two (IIIp5). The power a genuine particular thing expresses, then, must therefore be directed toward its own perseverance in being (IIIp6).

Pace Spinoza, the claim at IIIp4 that no thing can be destroyed except through an external cause is not clearly self-evident. Even assuming IIIp4 to be true, however, one might raise questions about Spinoza’s argument. Why is it that, just because a thing does not strive to destroy itself, that thing must therefore strive to persevere in being? A thing might it seems not strive for anything, or perhaps it might strive to do something which is neither perseverance nor self-destruction. Spinoza’s use of IP34 and Ip25c seems intended to rule out the first of these possibilities. Although Spinoza’s term ‘express’ (*exprimere*) is notoriously unclear, it may mean something like "is a particular form of." In that case, because particular things are expressions of God’s essence, his power, they must be particular forms of power. So there cannot be a thing which does not strive at all or, in other words, there cannot be a thing which is not any expression of power at all.

The second version of the objection, the version which notes the possibility that a particular thing as described in IIIp4 might strive for something other than either self-destruction or perseverance, remains a challenge to sympathetic readers of the *Ethics* however. The negation of IIIp6, that some thing does not strive to persevere in its being, where perseverance in being is understood as a particular end among many possible options, is perfectly consistent with the truth of IIIp4. After all, not striving to persevere in being, which IIIp6 rules out, is not the same thing as striving not to persevere in being, which IIIp4 rules out. A sympathetic reader of Spinoza might try to resolve the difficulty through an understanding of what

it means to strive to persevere in being, under which striving to persevere in being comes to mean just the same thing as striving to do something other than destroy oneself, in particular, striving to maintain a present state. (See Curley 1, 109, for an interpretation similar to this one.) This reading comes closer to making the argument from IIIp4 to IIIp6 seem valid, but it raises a new problem: that of reconciling this interpretation of striving with Spinoza's accounts of human motivation which follow from IIIp6. For Spinoza consistently regards sane human beings as finite modes who, beyond merely not trying to kill themselves, actively try to preserve themselves. People do not merely resist changes to whatever state they are in; they strive to change their states in order to know more and in order to live with a greater force. One of the main problems Spinoza faces, then, is reconciling the most plausible version of IIIp6 as an account of the natures of ordinary objects (under which IIIp6 represents a version of the principle of inertia) with the most plausible version of IIIp6 as an account of human nature (under which IIIp6 represents a version of psychological egoism).

1.2 The Striving Doctrine as an Account of the Natures of Particular Objects

Despite worries that one might have about the validity of Spinoza's argument, the doctrine has at least some claim to plausibility as an account of the nature of particular things. The *Ethics* stands badly in need of some account of what finite modes are, after all, and IIIp4 provides at least one interesting way of distinguishing genuine objects from mere constructs: if the thing in question destroys itself it is not a genuine object. Thus, by IIIp4, a thing which destroys itself--one might think a lit candle or a time bomb such a thing--is not a genuine object but a thing which does not destroy itself is. To the extent that IIIp4 makes most of the things we intuitively consider particular objects particular objects, it captures ordinary views. To the extent that it rules out some clear class of things (lit candles and time bombs), it represents a provocative philosophical thesis. The plausibility of the doctrine depends on whether we find that there really is reason to find basic metaphysical differences in kind between "things" which tend to destroy themselves and things which do not.

IIIp6 introduces, perhaps, a slightly different thesis about what it means to be a particular thing: a particular thing is one which strives to persevere in being. IIIp6's dependence upon IIIp4 suggests that this thesis means that any object will remain in the same state unless external causes affect it. Such a thesis appears to be a very general form of the principle of inertia, and, indeed, Spinoza seems to invoke the principle of inertia in the terms he uses at IIIp6. '*Conatus*' is a technical term of Cartesian physics, referring to an object's motion. Spinoza himself uses the term in this way in his exposition of Descartes's *Principles of Philosophy*. (Compare, for example, Descartes's *Principles* II, art. 37, III, art. 56 and III, art. 58 to Spinoza's exposition IIp14c, IIID3 and IIp17, respectively). Moreover, at IIIp6, in addition to using the term '*conatus*' again, Spinoza also uses the same phrase that he uses in framing the principle of inertia at IIp14 of his exposition of Descartes: "as far as it can by its own power" *quantum in se est*. (Note however that there is some controversy over how this phrase is to be understood: see Curley's footnote to IIIp6 in his translation and Garrett, 1999, note 2.) So there is a good textual basis for the conclusion that IIIp6 indeed has this meaning.

Apart from the question of how the principle of inertia can give us an understanding of human nature, this interpretation of IIIp6 raises two difficult questions. First, one might object that Spinoza puts too much philosophical weight on a single fact about the nature of things. After all, at IIIp7, Spinoza argues that a thing's striving to persevere in being is its essence. One should conclude from an understanding of IIIp6 as a new law of inertia, then, that IIIp7 simply means that an object's current state, in particular its current state of motion, is its essence. But why should a thing's tendency, in the absence of interference, to maintain its current state represent its essence? To hold such a view would be, seemingly arbitrarily, to elevate one natural property above others. On the face of it, there is no reason to suppose that a thing's tendency to continue to hold the properties it now holds is any more characteristic of or essential to it than any of its various tendencies to interact with other kinds of objects to produce particular kinds of effects.

Second, one might object that, IIIp6, understood as a restatement of the principle of inertia, extends a physical principle to mind without sufficient clarity. In stating the principle of inertia, both Descartes and Spinoza are careful to limit the claim to a claim about bodies. Spinoza, for example, in his definition of *conatus ad motum*, IIId3 of his exposition of Descartes, writes:

> By striving for motion we do not understand any thought, but only that a part of matter is so placed and stirred to motion, that it really would go somewhere if it were not prevented by any cause.

In addition to characterizing matter, however, IIIp6 is a foundational claim about the nature of mind and, in particular, about human psychology. There is a basis, in Spinoza's dual aspect theory and parallelism, for thinking that whatever is true about bodies is true about minds also (and see IIIp10 and IIIp11 for Spinoza's account of striving and the mind/body relation). Striving in physics, however, is understood as a tendency to a certain kind of motion, and motion seems, if anything does, to belong to bodies alone. So Spinoza needs to supply an account of the mental correlate to the physical "striving for motion." But IIIp6 leaves open the question of what it means for mind to strive. On this objection, the striving doctrine uses a kind of metaphorical language, the term 'striving', where a precise and literal account of what it is that is characteristic of mind is required.

1.3 The Striving Doctrine as an Account of Human Nature

Spinoza's naturalism benefits rhetorically from his use of the term '*conatus*' to describe the essences of human beings and other finite modes alike. For the term is not only a technical term of Cartesian physics. Cicero uses the term in *De Natura Deorum* (and other Roman and Greek Stoics use close cognates) in a psychological sense, referring to human desire, and Hobbes in his physiology uses the term to refer to the physical causes of human desire (*Leviathan* VI). So '*conatus*' has both broad, physical and specifically human, psychological connotations which help to make the gap between nature and the human mind appear narrow.

Whether Spinoza successfully capitalizes on his rhetorical skill, however, and draws a plausible account of the nature of the human mind out of his general account of the essences of finite modes depends upon IIIp9:

> III Proposition 9: Both insofar as the mind has clear and distinct ideas, and insofar as it has confused ideas, it strives, for an indefinite duration, to persevere in its being and it is conscious of this striving it has.

IIIp9 suggests that Spinoza is a psychological egoist of some sort. That is, it suggests that he believes that what human beings desire to do is to secure their own interests (construed here as perseverance in being). Indeed Spinoza goes on to define desire at IIIp9 as human striving (or appetite) together with the consciousness of striving. So clearly human desire for Spinoza is part of the striving for perseverance in being and thus shares its character.

There is some question, however, about what variety of psychological egoism Spinoza holds. Desire might be part of a striving for perseverance, after all, without all desires being desires for perseverance. One might have a strong instinctual desire for things which are instrumental to perseverance in being without desiring perseverance itself, for example. Or one might desire perseverance in being but also desire other kinds of things.

IIIp9 might be supposed to support a very strong version of psychological egoism, orthodox egoism (perhaps Delahunty, 221, holds this view). Orthodox egoism, is the view that human beings are always consciously selfish. Under this view, A consciously desires only those objects which benefit A, B desires only those objects which benefit B, and so on for all human beings. At IIIp9, Spinoza writes that the human mind seeks to persevere in being both insofar as it has clear and distinct ideas and insofar as it has confused ideas. It is natural to understand this claim to mean something like the following:

> Sometimes people do things which conduce to their perseverance and other times people do things which fail to so conduce. In both types of case, though, people desire to persevere. When I do something that fails to help me to persevere, it's because the ideas on which I based my action were confused; that is, I thought I knew what would help me to persevere, but I was wrong. When I do something that does help me to persevere, though (unless I have simply been lucky in acting from an inadequate idea), it is because I acted on clear and distinct ideas or, in other words, genuine knowledge about what would help me to persevere.

The categorical language Spinoza uses in the Appendix to Part I provides explicit support for this interpretation of IIIp9: "men act always on account of an end, viz. on account of their advantage, which they want." Moreover there are other important passages in Spinoza's works which are strongly compatible with the interpretation of Spinoza as an orthodox egoist. These include *Ethics* IVp8d, and his political writings, especially *Ethics* IVp36s2, and his *Political Treatise*, chapter 2)

Other evidence suggests that Spinoza is not an orthodox egoist, however. In particular, there is reason to question whether the argument of the *Ethics* commits Spinoza to the account of actions following from confused ideas that the interpretation of IIIp9 above attributes to him. Part of IIIp39s concerns those agents who are the most confused. That passage is useful because it describes explicitly the conscious thought-processes that precede action:

> Though men are liable to a great many affects, so that one rarely finds them to be always agitated by one and the same affect, still there are those in whom one affect is stubbornly fixed. For we sometimes see that men are so affected by one object that, although it is not present, they still believe they have it with them. When this happens to a man who is not asleep, we say that he is mad or insane. Nor are they thought to be less mad who burn with Love,and dream, both night and day, only of a lover or a courtesan. For they usually provoke laughter. But when a greedy man thinks of nothing else but profit, or money, and an ambitious man of esteem, they are not thought to be mad, because they are usually troublesome and are considered worthy of Hate. But Greed, Ambition, and Lust really are species of madness, even though they are not numbered among the diseases.

In this scholium (and in other discussions of monomania such as III Definition of the Affects, XLVIII and IVp20s) Spinoza describes a variety of possible ends of human action, none of which is perseverance in being. Moreover, lest one think that the greedy man seeks profit because he mistakenly believes that it leads to perseverance, Spinoza emphasizes the point that it is always one and the same object that obsesses these men.

IIIp39s suggests that Spinoza holds a different kind of view, predominant egoism, the view that most people, most of the time consciously desire perseverance in their own being. The particular type of predominant egoism that IIIp39s suggests introduces important aspects of Spinoza's ethical theory: if the most confused people, people addled by greed or lust or ambition are those who always seek something other than perseverance in being, then perhaps Spinoza's view is that, for any of us who act on some similar sentiments occasionally, we do so just to the extent that we also have confused ideas. Thus human beings are predominantly egoistic because, by and large, we act on clear and distinct ideas: it is rational to seek to persevere in being (see also what "reason demands" at IVP18S). But we are not orthodox egoists, on this interpretation of Spinoza as a predominant egoist, because we are not fully rational. To the extent that we have confused ideas, we may indeed consciously pursue ends other than perseverance in being. On this interpretation of Spinoza, there is a right (or at least a rational) end to pursue--perseverance in being--and other ends are wrong (or at least irrational).

IVp20 provides support for this interpretation of Spinoza's predominant egoism:

> IV Proposition 20: The more each one strives, and is able, to seek his own advantage, i.e., to preserve his being, the more he is endowed with virtue; conversely, insofar as each one neglects his own advantage, i.e., neglects to preserve his own being, he lacks power.

Here Spinoza explicitly admits that a person may "neglect his own advantage." So IVp20 apparently contradicts the orthodox egoism of I Appendix. Moreover, IVp20 states that, to the extent that a person does seek perseverance in being, that person is virtuous. Virtue has a metaphysical connotation in the *Ethics*. A thing's virtue is just the same as its power (IVd8). But the term undeniably has moral connotations as well. So IVp20 suggests, as IIIp39s does, that consciously trying to preserve oneself is right and neglecting to preserve oneself is wrong.

IIIp9 admits of various interpretations. However, the weight of the textual evidence supports the view that he is a predominant, not an orthodox, egoist. Any particular human desire, then, even a desire that is not a desire for perseverance in being or its means, must on Spinoza's view be related to perseverance in being in some way (by IIIp6 and IIIp9s). Spinoza's association of desires for things other than perseverance in being in passages such as IIIp39s and IVp20 suggests moreover that such desires are part or product of confusion. So passionate desires, for Spinoza, are often desires for things other than perseverance in being, although they may be confused desires for perseverance as well (see IVp63s2 and other discussions of fear).

For discussions of the ancient roots of the striving doctine, see James and Wolfson. Lachterman covers Spinoza physics and his use of Descartes. Most book-length interpretations of the *Ethics* include detailed accounts of Spinoza's view of human nature. One recent account of interest is Yovel's. The best recent discussions of psychological egoism come in the context of the interpretation of Hobbes, to whom Spinoza is sometimes compared. See Kavka and Hampton.

2. The Affects

Spinoza's account of the affects (*affectus*) of the human mind is a response to one of the central problems for his naturalism. It is an attempt to show how the wide range of desires and emotions of the human mind can be produced by something which follows the order of nature. At the start of Part III (see also Chapter 2 of his *Political Treatise*), Spinoza notes that traditional accounts of the passions, with the exception of Descartes's, have rested on the assumption--one wholly baseless in Spinoza's view--that human beings are a separate "dominion" within the dominion of nature, with different kinds of constituents and governed by different sorts of laws. Spinoza's project continues what he finds to be Descartes's important innovation: seeking "to explain human affects through their first causes." So his account of the affects may be most profitably compared to Descartes's in his *Passions of the Soul*. It may also be usefully compared to accounts in the writings of Hobbes (especially *Leviathan* VI), a contemporary who shared many of Spinoza's philosophical commitments, or to some of the "traditional accounts" which Spinoza faults, such as Aquinas's *Summa Theologiae*. (Aquinas's treatments of the passions appear mainly between Ia75 and 2a2ae189.)

Spinoza, though, because he denies freedom of the will, is more thorough than Descartes in his commitment to naturalism. This commitment makes the task Spinoza undertakes in the *Ethics* an even

more dramatic revision of traditional understandings of the passions than that which Descartes produced. So Spinoza, even more than Descartes, is open to the sort of objection which traditional authors, those to whom it seems beyond question that human beings are outside nature, might raise: how can the full range of human psychological phenomena be produced by natural causes? For the argument of the *Ethics* to succeed, Spinoza must produce, first, an account of how human desires and emotions might be a part of nature as he has presented it in the *Ethics* and, second, a description of those human desires and emotions which is plausibly complex, that is, plausibly consistent with our experience of ourselves. The subsections which follow address these issues in turn.

2.1 The Affects and Striving

The human affects, for Spinoza, are a part of nature insofar as each can be redescribed in terms of striving, a property which all particular things in nature share. Desire and its varieties are striving itself, under a certain description. Human passion, in whatever form it takes, is for Spinoza a decrease in the power with which the we strive. Active affects are each increases in the power with which we strive.

Spinoza introduces the first of his primary affects, desire, at IIIp9s, directly after introducing the doctrine of human striving, which, in its most general form, he calls appetite.

> III Proposition 9, Scholium: ...Between appetite and desire there is no difference, expect that desire is generally related to men insofar as they are conscious of the appetite. So desire can be defined as appetite together with consciousness of the appetite.

Thus Spinoza identifies human desire with human essence and especially with consciousness of one’s essence, the striving for perseverance in being. Spinoza’s theory of consciousness is notoriously incomplete, and it is not clear whether, on his view, things other than human beings have consciousness. For human beings, at least, however, what seems to us to cause us to act, our desire, does, on Spinoza’s view, do just that. If I am asked for the proximate cause of my action in picking up my coffee cup, for example, I will respond that it was my desire for the coffee. In identifying the cause of human action, striving, with conscious desire, then, IIIp9s vindicates common sense to a degree. Had Spinoza identified desire with something other than striving, then he would commit himself to the view that my desire does not in fact cause me to pick up the cup. (Desire for Spinoza, in its narrow definition at IIIp9s, is psycho-physical and, in its broader definition at III, Definitions of the Affects, I, may be either. So, this example, perhaps despite appearances, does not run afoul of Spinoza’s denial of mind-body interaction.)

IIIp9s, then, goes a long way toward showing how the universal striving doctrine can be the basis for an account of human desire. A serious problem remains, however. Although we tend to see desire as the proximate cause of action, we tend also to conceive of desire as involving teleology or final causes. If desire causes me to pick up the cup, what causes my desire? The common-sense answer is teleological: I have, as an end, coffee, and I am, in a sense, drawn toward it. Spinoza, though well-aware of the fact that we commonly suppose that there are teleological causes of our actions, denies their reality:

> What is called a final cause is nothing but a human appetite insofar as it is considered as a principle, or primary cause, of some thing. For example, when we say that habitation was the final cause of this or that house, surely we understand nothing but that a man, because he imagined the conveniences of domestic life, had an appetite to build a house. So habitation, insofar as it is considered as a final cause, is nothing more than this singular appetite. It is really an efficient cause, which is considered as a first cause, because men are commonly ignorant of the causes of their appetites.

While he can accommodate, in a general way, the common-sense view that desire causes action, then, Spinoza must deny the other common-sense view that desire operates teleologically, and must explain what the ends of human action are, why they seem to human beings to explain actions, and what their real relation is to the processes of efficient causation involved in human behavior. (For an argument against this view, the view that Spinoza denies all teleology, see Garrett 2.)

For these tasks, Spinoza introduces the other primary affects and a number of psychological laws associated with them. He introduces the primary passions at IIIp11s.

> III Proposition 11, Scholium: We see, then, that the mind can undergo great changes, and pass now to a greater, now to a lesser perfection. These passions, indeed, explain to us the affects of Joy [*laetitia*] and Sadness [*tristitia*]. By Joy, therefore, I shall understand in what follows that passion by which the mind passes to a greater perfection. And by Sadness, that passion by which it passes to a lesser perfection.

The perfectionist language Spinoza uses is important for an understanding of the basis for ethics that he finds in psychology. Here, however, it may be understood in terms of striving. An increased power to persevere in being is for Spinoza a transition to greater perfection and a decreased power is a transition to lesser perfection (see IIIp11, the end of IV Preface, and especially III, Definitions of the Affects, III, Exp.). So joy is the passion one experiences in the transition to an increased power to strive, and sadness is the passion one experiences in the opposite transition. Spinoza thus provides, in his account of the affects, the basis for an explanation of how it is that introspection into our conscious experience of desire might fail to bring us accurate knowledge of our own psychological processes. Our conscious experience, both in reacting to ourselves and external objects and also in forming our desires, has an emotional component: we experience joy and sadness and varieties of these. But we may be unaware of why we feel joy or sadness or why, really, we desire what we desire. So Spinoza writes repeatedly, in the context of his criticisms of teleological reasoning and the introspective experiences of free will or mind/body causation (e.g., at IIIp2s): "men are conscious of their actions and ignorant of the causes by which they are determined."

Spinoza offers an explanation of the apparent teleology in desire, in particular, at IIIp28:

> We strive to promote the occurrence of whatever we imagine will lead to joy, and to avert

> or destroy what we imagine is contrary to it, or will lead to sadness.

Spinoza reserves the term 'imagine' [*imaginor*] for the description of conscious states, so IIIp28 describes, at least in part, the objects of desire. If I imagine that coffee will lead to joy, then I will desire that joy and so that coffee. IIIp28, strictly speaking, is not an exhaustive characterization of objects of desire. It implies only that we desire anything which we imagine will lead to joy and are averse to whatever we imagine will lead to sadness and not that we might not have other kinds of desires also, desires unrelated to either joy or sadness. A review of the particular forms of desire Spinoza catalogues in Part III suggests, however, that the view is still stronger than the limited claim of IIIp28: it seems that Spinoza does hold that anything I desire will be a thing which leads to joy or sadness.

What seems on introspection, then, to be a teleological cause of action, the end represented by an object of desire, is for Spinoza a peculiar manifestation in consciousness of striving, which in turn is the genuine (i.e., efficient) cause of action. I reach for the cup of coffee, I may think, because the joy that I anticipate in the coffee "pulls" me to it; in fact, however, I reach for the coffee because my characteristic striving (perhaps as a partial cause in combination with other partial causes such as the memory of past cups--IIIp36) has that effect. It "pushes" me toward the cup.

2.2 The Variety of Affects

Perhaps the psychological view that Spinoza introduces at IIIp28 is susceptible to the sort of objection which one might raise against psychological hedonism, the view that human beings only desire pleasure, the avoidance of pain, and what is instrumental to these things. It may seem to some people that IIIp28 is not consistent with their own experience of their motives in acting. So, someone with a strong sense of justice might say:

> It's not that I like Jones or would get any joy from having him walk. I think the guy's a jerk, and I hate to think of him out on the street. But I want him to be released from prison. He simply did not do what he's been convicted of, so he should be set free.

On the basis of introspective observations like this one, one might complain that, even if Spinoza's account of the affects can be shown to be consistent with the general theory of striving as it is presented at IIIp6, still the theory of affects is not itself a realistically complex account of human desire, since it cannot account for desires like this one which do not have emotional components. The plausibility of Spinoza's view depends upon the extent to which it can reasonably redescribe this desire, and other similarly troubling desires,in ways which are consistent with IIIp28.

Spinoza attempts to show that there many varieties of joy, sadness, and desire. Thus he might attempt to address the complaint by showing that its author offers a slightly inaccurate description of the situation:

> The author denies liking Jones. Let us suppose even that he hates Jones. Even so, that does

> not mean that the author anticipates no joy at all in Jones's release. Knowing that his society is just in at least this one case may reassure the author of the complaint to some degree that he might be fairly treated himself. So it might be a kind of hope (IIIp18s2) which motivates the desire. Or perhaps there are people the author likes, his fellow citizens generally perhaps, to whom he wishes a similar peace of mind. The author may want the release in order to find a kind of joy, whether it be out if his ambition to please them or simply out of his human kindness (IIIp29s) or nobility (IIIp59s), in the well-being of these other people.

Far from insisting that there is one particular kind of emotion that moves people, Spinoza writes that there is an innumerable variety of affects:

> III Proposition 56: There are as many species of Joy, Sadness and Desire, and consequently of each affect composed of these (like vacillation of mind) or derived from them (like love, hate, hope, fear, etc.), as there are objects by which we are affected.

IIIp51 assures us, moreover, that the same object might affect different people, or even the same person at different times, in different ways. So Spinoza protects himself from the charge that IIIp28 is obviously false (albeit at the risk of forwarding an unfalsifiable psychological claim) by arguing that, despite the seeming simplicity of that proposition, it cannot be falsified by the great variety of conscious human motives.

Although Spinoza repeatedly insists that the variety of affects is innumerable, he nevertheless does characterize, in his own terms, many of the traditional passions, each of which is either a kind of joy, sadness or desire or a hybrid of two different affects. A few Spinoza's particular accounts are notable.

Pity (*commiseratio*) is for Spinoza a species of sadness, sadness that arises from injury to another (IIIp22s), and so to feel pity, on Spinoza's view is to experience a decrease in one's own power to persevere in being. If continued perseverance in being is what virtuous agents seek, then, Spinoza will be commmited to the view that pity is not a virtue. Indeed, Spinoza writes at IVp50c, "A man who lives according to the dictates of reason, strives, as far as he can, not to be touched by pity." So Spinoza stands apart from traditional Christian views on this subject (and also on the subjects of humility and repentence), and with Hobbes who conceives of pity in *Leviathan* VI as a kind of grief and so a kind of displeasure. This revisionary tendency in his thought is tempered, however, by IIIp54, where he presents pity, and also the other traditional Christian virtues of humility and repentence, as, if not genuine virtues themselves, at least means to virtue, by which people are made more able to come to learn to follow the dictates of reason.

Self-esteem (*acquiescentia in se ipso*) which Spinoza introduces at IIIp30 as Joy accompanied by the idea of oneself as an internal cause becomes an important part of Spinoza's ethical theory, a species of which is even blessedness (*beatitudo*, see IV, App. 4), the highest form of human happiness. Human beings, as finite modes cannot, on Spinoza's view, avoid affecting and being affected by external objects.

Nevertheless, Spinoza's emphasis on self-esteem, and, in his ethical theory, on self-knowledge, suggests that to the extent we are able to bring about effects, including our own emotions, as whole or adequate causes of those effects, we are better off. His remarks concerning the impossibility of controlling the passions and the desireability of controlling them nevertheless to the extent that we can (V Preface) similarly emphasize the ethical importance of self-knowledge and freedom from external influences.

Finally, **active joy** and **active desire** which Spinoza introduces at IIIp58 represent a separate class of affects notable both for their novelty against the background of traditional accounts of the passions and also for their importance to Spinoza's ethical arguments of Parts IV and V. On traditional accounts of the passions, even Descartes's (*The Passions of the Soul*, I.1), actions and passions are the same thing, regarded from different perspectives: when A does X to B, X is an action for A but a passion for B. For Spinoza, however, anything which follows in a person where that person is an "inadequate" or partial cause of the thing, is a passion, and anything that follows where a person is an "adequate" or whole cause of the thing is an action. Thus Spinoza's class of active affects places a strong emphasis on people's roles as whole causes of what they do; because it becomes for Spinoza ethically important that a person be active rather than passive, that emphasis raises a host of questions about the extent to which a person, a particular thing interacting constantly with other things and indeed requiring some of them for sustenance, can come to resist passion and guide himself by means of joy and the active desires.

Because joy and sadness as introduced at IIIp11s are passions, all of the desires arising from them or species of them are passive as well, that is, they are not desires which arise from a person's striving alone but only as a partial cause in combination with other, ultimately external causes. Active joy, which must include at least some types of warranted self-esteem, and active desires, among which Spinoza lists at IIIp59s tenacity (*animositas*) and nobility (*generositas*) are wholly active however; that is, they are emotions and desires that people have only insofar as they are adequate causes, or genuine actors. (Notice that sadness cannot ever be an active emotion. People cannot, insofar as they are active bring it about that their power of acting is decreased, so passive sadness, unlike passive joy and desire, has no active counterpart.)

Of these active affects, the most important for an interpretation of Spinoza's ethics and political philosophy is likely nobility. Spinoza's predominant egoism, together with some of his still stronger statements of psychological egoism such as that at I Appendix, suggest that individuals are not, or are not often, altruistic. Moreover, his ethics, with its emphasis on self-esteem and self-knowledge appears in ways to be an individualistic one: the good, when I attain it, is a perfection of myself, not of society or the world. However, nobility, as Spinoza defines it, is a wholly active desire to join others in friendship and to aid them. Spinoza needs, in his ethics, to explain how aiding others is virtuous, and, in his political theory, to explain why a person, even a rational one, would want to come to the aid of others.

Further reading: For discussions of Spinoza's theory of affects in a comparative framework, see Hoffman and James (2). For discussions of the relationship between striving and the affects, see these works and also Davidson,and Schrijvers. Bennett (2), Curley (2), Della Rocca and Garrett (2) discuss Spinoza's views on teleology. Lloyd offers accounts of various particular affects. For a detailed discussion of self-esteem, see Rutherford.

3. The Psychological Basis for a Theory of Value

Spinoza’s insistence that human beings not be treated as a dominion within a dominion includes a commitment to ethical naturalism also. Just as he insists that the human mind must be explicable in terms of the laws which govern nature, so he insists that ethical properties, which he sometimes characterizes as human "modes of thinking," be explicable in terms of natural ones. The theory of the affects serves Spinoza’s ethical naturalism by introducing explanations of ethical concepts, most importantly the concepts of good, evil, and perfection, in psychological terms. In his ethics, Spinoza in some way "retains these words," although he may be understood to do so under some formal refinement or revision of them (See IV Preface). So his discussions of good and evil and of human perfection in Part III provide the basis for the formal ethical argument which follows in Parts IV and V.

3.1 Good and Evil as Modes of Thinking

Before defining ‘good’ and ‘evil’ formally, Spinoza at IV Preface regards good and evil as labels, "modes of thinking," that human beings apply to things but which really reveal little about the things to which they are applied:

> As far as good and evil are concerned, they also indicate nothing positive in things, considered in themselves, nor are they anything other than modes of thinking, or notions we form because we compare things to one another. For one and the same thing can be good, and [evil], and also indifferent. For example, Music is good for one who is melancholy, [evil to] one who is mourning, and nether good nor [evil] to one who is deaf.

The phrase "nothing positive in things" means perhaps that an observer of people would find that ‘good’ and ‘evil’, as people use them are two place predicates rather than one place predicates. If Martha calls music evil, then, what that indicates to one who knows about the human use of these terms is that the music is evil to Martha. Moreover, since the same music can be good or evil for different people, or for people in different states, the two place predication reveals more about Martha than about the music. It must be some fact about the person, rather than some fact about the thing called good or evil, that is of central importance to the understanding of the label.

IIIp9s suggests that the fact about the person which the label reveals is her conative state:

> It is clear that we neither strive for, nor will, neither want, nor desire anything because we judge it to be good; on the contrary, we judge something to be good because we strive for it, will it, want it, and desire it.

Spinoza finds that the designation of a thing as good follows from a person’s conative state: Martha is

averse to music and therefore she calls it evil. Should the music become good to another person, or perhaps Martha herself in different circumstances, it would not be because the music has changed, but because the person's conative state is different: she desires the music. (This analysis of the good is remarkable similar to Hobbes's at *Leviathan VI*. Maimonides, another of Spinoza's influences, also has a similar analysis: *Guide of the Perplexed*, III, 13.)

IIIp39s offers a similar analysis. There Spinoza writes, in the same vein as IIIp9s, that, "each one, from his own affect, judges, or evaluates, what is good and what is [evil]...So the greedy man judges an abundance of money best, and poverty worst. The ambitious man desires nothing so much as esteem and dreads nothing so much as shame." However, IIIp39s also uses Spinoza's theory of the affects to introduce new definitions of good and evil:

> By good here I understand every kind of joy, and whatever leads to it, and especially whatever satisfies any kind of longing, whatever that may be. And by evil, every kind of sadness and especially what frustrates longing.

IIIp28, the proposition establishing Spinoza's doctrine that human beings desire whatever will bring joy and are averse to whatever will lead to sadness, allows Spinoza to connect the objects of any human desire with joy or the avoidance of sadness. So, if it is true that we call a thing good only if we desire it, then it will also be true that anything we call good will be joy or what leads to it. Understood in this way, IIIp39s simply restates the doctrine of IIIp9s in light of IIIp28.

However, Spinoza might be extending rather than merely restating his position at IIIp39s. Every kind of joy we experience is not presumably a result of conscious desire, and Spinoza allows at IIIP39s that these instances of joy (i.e., those which do not satisfy any kind of longing) are also good. So not only is whatever Martha desires good for her, but, in addition, anything which she does not desire but which nonetheless might bring her joy will also be good. IIIp39s therefore identifies the good and evil for a person with broader classes of things, and makes possible an analysis of good and evil in terms of something other than an individual person's current desires. Because, in giving an account of the right way of living in Parts IV and V, Spinoza presumably urges people to desire and do things in a way different from what they desire and do already, this broadening of the application of the terms 'good' and 'evil' (to apply to things other than what people presently desire or are averse to) contributes to the plausibility of his ethical naturalism.

3.2 The Psychological Basis for Perfectionism

The meaning of 'perfection' (*perfectio*) in various passages of the *Ethics* is obscured by the fact that Spinoza uses the term both in what he takes to be its common meaning and also in a narrow, formal sense. In some passages, such as IV Preface, Spinoza treats perfection, like good and evil, to be a label that people apply to things, to be explained in terms of those people's use of the label: people call a thing perfect which conforms to the model of the thing that they create for themselves. In other passages, however, Spinoza treats perfection as whatever is "positive" or "real" in a thing, a genuine propety, and

this concept forms part of his formal apparatus (IId6).

Both senses of the term occur in Spinoza's analysis of human perfection. At IV Preface Spinoza invokes a concept of perfection based upon a model of human nature that we set before ourselves. And Spinoza describes perfection of the human mind in terms of its power of thinking, as we have already seen, at IIIp11 and its scholium: the mind's power of thinking is its perfection; joy is an increase in that power or a passage to a greater perfection; and sadness is a decrease in that power or a passage to a lesser perfection.

Thus Spinoza has two different accounts of human perfection which might contribute to the perfectionist language of the ethical argument that he develops in various ways in Parts IV and V. Although the first account contributes to both Spinoza's formal definitions of good and evil and also, probably, to the "free man" propositions of Part IV, it is perhaps the second account which is of greater importance. It, after all, resonates with Spinoza's account of the good at IIIp39s, and so comes to form part of a consistent moral view: if the good is any form of joy (IIIp39s) and joy is the passage to a greater perfection (IIIp11s), then the good is whatever makes us more perfect. On the other hand, the first account might imply a different set of norms from IIIp39s: it seems that we may have different models of human nature that we set before ourselves, and that they may or may not include the various things that give us joy. Perhaps the formal account of perfection at IId6 and later at IIIp11 give Spinoza a means of reformulating the idea of perfection as a model of human nature in a way which reconciles the two senses of the term: the ideal we set before ourselves will be a person who possesses the greatest possible power of action. This would be, in effect, to correlate our systematically distorted ways of perceiving ourselves--as free agents pursuing as an end a model of human nature--with the causes that really determine our actions.

Further Reading: Curley (1), Delahunty, Garrett (1) and Yovel offer accounts of Spinoza's ethical language as it relates to his psychology. For a discussion of Spinoza's views on perfection, see Garrett (1), Allison and Wolfson.

Law and Ideology

If law is a system of enforceable rules governing social relations and legislated by a political system, it might seem obvious that law is connected to ideology. Ideology refers, in a general sense, to a system of political ideas, and law and politics seem inextricably intertwined. Just as ideologies are dotted across the political spectrum, so too are legal systems. Thus we speak of both legal systems and ideologies as liberal, fascist, communist, and so on, and most people probably assume that a law is the legal expression of a political ideology. One would expect the practice and activity of law to be shaped by people's political beliefs, so law might seem to emanate from ideology in a straightforward and uncontroversial way.

However, the connection between law and ideology is both complex and contentious. This is because of the diversity of definitions of ideology, and the various ways in which ideology might be related to law. Moreover, whilst the observation about law's link with ideology might seem a sociological commonplace, the link between law and ideology is more often made in a critical spirit, in order to impugn law.

At issue is an understanding of ideology as a source of manipulation. Law as ideology directs its subjects in ways that are not transparent to the subjects themselves; law, on this view, cloaks power. The ideal of law, in contrast, involves a set of institutions that regulate or restrain power with reference to norms of justice. Thus the presence of the ideological in law must, in some sense, compromise law's integrity. Not only is the view of law as ideology at odds with a lot of mainstream thinking about law, it seems difficult to reconcile with the central philosophical positions on the nature of law, e.g. a positivist conception of law as a set of formal rules, or a natural law conception where law is identified with moral principles.

1. Liberal Concepts of Ideology

What is ideology? The term was likely coined by the French thinker Claude Destutt de Tracy at the turn of the nineteenth century, in his study of the Enlightenment. For De Tracy, ideology was the science of ideas and their origins. Ideology understands ideas to issue, not haphazardly from mind or consciousness, but as the result of forces in the material environment that shape what people think. De Tracy believed his view of ideology could be put to progressive political purposes, since understanding the source of ideas might enable efforts on behalf of human progress.

Ideology today is generally taken to mean not a science of ideas, but the ideas themselves, and moreover ideas of a particular kind. Ideologies are ideas whose purpose is not epistemic, but political. Thus an ideology exists to confirm a certain political viewpoint, serve the interests of certain people, or to perform a functional role in relation to social, economic, political and legal institutions. Daniel Bell dubbed ideology 'an action-oriented system of beliefs,' and the fact that ideology is action-oriented indicates its role is not to render reality transparent, but to motivate people to do or not do certain things. Such a role may involve a process of justification that requires the obfuscation of reality. Nonetheless, Bell and other liberal sociologists do not assume any particular relation between ideology and the status quo; some ideologies serve the status quo, others call for its reform or overthrow.

On this view, ideology can shape law, but a variety of ideologies might be vying for legal mastery; there is no necessary connection between law and a particular ideology. Law need not be understood as compromised, since law being ideological might just refer to the institutions of popular sovereignty, where public policy reflects citizens' principles and beliefs; ideology would in that case just be a shorthand way of referring to the views of citizens that are legitimately instantiated in the laws of the land. Nonetheless, Bell argued that a postwar consensus on capitalism and liberal democracy might spell the 'end of ideology.'

2. Radical Concepts of Ideology

A more critical understanding of law's relation to ideology, and the role and purposes that ideology serves, is found in the writings of Karl Marx and Friedrich Engels. Like De Tracy, Marx and Engels contend that ideas are shaped by the material world, but as historical materialists they understand the material to consist of relations of production that undergo change and development. Moreover, for Marx and Engels, it is the exploitative and alienating features of capitalist economic relations that prompt ideas they dub 'ideology.' Ideology only arises where there are social conditions such as those produced by private property that are vulnerable to criticism and protest; ideology exists to inure these social conditions from attack by those who are disadvantaged by them. Capitalist ideologies give an inverted explanation for market relations, for example, so that human beings perceive their actions as the consequence of economic factors, rather than the other way around, and moreover, thereby understand the market to be natural and inevitable. Members of the Frankfurt School such as Jurgen Habermas drew

on the Marxist idea of ideology as a distortion of reality to point to its role in communication, wherein interlocutors find that power relations prevent the open, uncoerced articulation of beliefs and values.

Thus ideology, far from being a science, as De Tracy contends, or any set of action-oriented beliefs as Bell puts it, is rather inherently conservative, quietist, and epistemically unreliable. Ideology conserves by camouflaging flawed social conditions, giving an illusory account of their rationale or function, in order to justify and win acceptance of them. Indeed, on this view of the ideological role of law, in a just society there would be no need for a mystifying account of reality, and thus no need for law. The concept of law as ideology is thus central to the Marxist view that law will wither away with the full flowering of communism.

The negative view of ideology taken by Marxists might suggest a crude conception where legal ideology is a tool cynically wielded by the powerful to ensure submission by the powerless. However, it offends the 'conception of right,' Marx argues, if 'a code of law is the blunt, unmitigated, unadulterated expression of the domination of a class.' And because ideology such as law takes a formal and normative form, the powerful are in its grips too, persuaded by an account of the inevitable and just order from which they profit. Moreover, ideology is no mere fiction; it is produced by real social conditions and reflects them. Ideology thus must succeed in constituting a consensus about capitalism, and it must do so by giving expression to capitalism's recognizable features. Equality before the law, for example, is both elicited by, and reflects, the reality of capitalist economic relations, even if it is an equality that is formal and incomplete. Consent will not be forthcoming if legal ideology bears no relation whatsoever to the social conditions it seeks to justify. The idea that ideology inverts reality is important here. In his camera obscura metaphor in *The German Ideology*, Marx contends that reality appears upside down in ideology, much like the photographic process provides an inverted image. The inverted image is telling; it is a recognisable depiction of reality, even if it is at the same time a distorted one. Karl Mannheim elaborated further on the idea of the complex relation between reality and ideology by pointing to the human need for ideology. Ideologies are neither true nor false but are a set of socially conditioned ideas that provide a truth that people, both the advantaged and the disadvantaged, want to hear.

In the 1920s, American jurisprudence came under the influence of another version of the critical view of ideology and law. The school of legal realism abandoned Marx's specifically historical materialist explanation, but took up the idea that social forces outside the law are central in determining what the law is. Realists opposed traditional 'formalist' accounts of adjudication, where judges are understood to rely on uniquely and distinctively legal materials in rendering their judgments. Instead, the realists contended that law is inherently indeterminate, and thus judicial decisions must be explained by factors outside the law. Ideology emerges as one kind of realist explanation, where judicial decisions are the effect of political ideas, be they of the judge, the legal profession more generally, societal elites, or majority public opinion. The realists aligned their critique of law with a progressive politics. The inevitable influence of factors external to the law meant that social and political changes augured by the emerging welfare state were no threat to the purity of law. Indeed, the expanding regulative power of the administrative state would make it more likely that the influences on the law were now those of popular sovereignty and social justice, rather than the more nefarious influences of the past.

The view that law is a reflection of ideology was taken up again in the 1970s and 80s, with the emergence of the Critical Legal Studies movement. Critical Legal Studies was a radical movement of lawyers shaped by a number of influences: the Marxist and realist traditions; the philosophical perspective of 'deconstruction;' and the politics of issues such as feminism, environmentalism and anti-racism. The movement takes up the realist idea that law is fundamentally indeterminate, and echoes Marxist views about the ways in which the interests of the powerful shape law. Exponents offer some astute observations about the way law is taught and practiced to give the misleading impression of law's certainty and legitimacy. Particular legal doctrines are targeted for papering over the inconsistent and arbitrary features of legal decision-making; the rule of law, for example, is criticized for a naïve view of the form of law as unaffected by law's content and the social context in which law operates. The indeterminacy of law can produce a variety of results; Duncan Kennedy, for example, points out the surprising ways in which the ideology of formal legal reasoning can remedy injustice, even if ideology often disables such remedies as well.

3. Ideology and the Sources of Law

The well-known debate about the sources of law appears to be radically undercut by a view of law as ideology. The sources debate has usually been posed in terms of the extent to which morality is intrinsic to the definition of law. Natural lawyers argue that what is law must partly depend on moral criteria. Following Thomas Aquinas, the traditional criteria have not strayed far from the teachings of the Roman Catholic Church, but more recent natural law arguments, such as those of Lon Fuller and Ronald Dworkin, have proffered secular standards emanating from the procedural ideals of the rule of law or the constitutionalism of American liberalism. All natural lawyers, however, are agreed that what the law is must be determined, in some sense, by what the law ought to be.

Positivists, in contrast, have argued that what is law is determined only by the institutional facts internal to a legal system, facts that may or may not meet moral standards. Early positivists, such as Thomas Hobbes and John Austin, argued that even the legitimacy of law did not depend on moral criteria; law must be obeyed, however much it falls short of moral ideals. More recent exponents, such as H.L.A. Hart and Joseph Raz, have offered as a justification for the positivist position the idea that because what is law is a factual question, law's legitimacy can be determined by moral criteria outside the law that might recommend disobedience. All positivists, however, are agreed that what the law is and what it ought to be should be kept distinct.

The natural law and legal positivist positions are united, however, in the aim to provide a concept of the essence of law. This endeavour supplies them with a common enemy in the view of law as ideology, which finds trying to determine the essence of law as fundamentally misconceived. After all, if law is inevitably shaped by ideas emanating from power relations outside of the law, then law has no essence, be it moral or institutional. If law is reduced to ideology, or seen as its mere effect, then legality looks contingent and unprincipled, having no necessary content or definition, no intrinsic character. If law both mirrors and distorts the realities of power, it is power, not principles of legality, which tell us what law is. Thus for most mainstream legal theorists, the ideological is no necessary feature of the law, and law

should certainly not be defined according to the radical conception where intrinsic to law is a mystification of reality, or an obfuscation of social relations in order to exact compliance.

The picture is more complicated, however. The ideology position does, after all, have some affinities with rival views on the sources of law. The ideology view concedes to the positivist, for example, that law emerges from the practices of society, though the practices are extra-legal -- political, economic and social -- rather than the practices of institutional facts internal to a legal system. Social forces are ultimately determining of the content and form of a legal system. Indeed, the Marxist Louis Althusser's idea of ideological state apparatuses has a definite positivist flavour in its insistence that political reality can be exhaustively described by reference to structures rather than norm-bearing agents. We might expect that the radical exponent of ideology would resist the combination of a positivist-ideology view. The radical would find in the positivist emphasis on institutions a too uncritical attitude to the ideological structures that shape those institutions. But it seems possible that the positivist position could be revised to remove any ascribing of legitimacy to the institutions that define law in order to accommodate the critique of the radical ideology position.

As for the natural law position, the ideology view concedes to the natural lawyer that law is normative. What is ideology, after all, but a set of values and ideals? However, on the ideology view, the norms are defined in terms of the interests they serve, rather than the justice they embody. Law is normative, but it is certainly not moral, the ideology view insists against the natural law view. The critical aspect of the radical ideology view suggests an impasse between the natural lawyer and the ideology position that is more difficult to overcome than in the positivist case.

Of course, natural lawyers and positivists could quite easily find room for the liberal view of ideology as an action-oriented system of beliefs as a supplement to their views about the sources of law, in the sense that ideology is part of the sociological landscape to which their concepts of law apply. Natural law can find popular expression in a society's ideology, and positivist legal institutions might reflect ideological beliefs.

4. Ideology and the Rule of Law

All this points to another and related tension. This is the tension between the ideology view and the concept of the rule of law, the centrepiece of a liberal legal order. At their most basic, the terms the rule of law, due process, procedural justice, legal formality, procedural rationality, justice as regularity, all refer to the idea that law should meet certain procedural requirements so that the individual is enabled to obey it. These requirements center on the principle that the law be general, that it take the form of *rules*. Law by definition should be directed to more than a particular situation or individual; the rule of law also requires that law be relatively certain, clearly expressed, open, prospective and adequately publicised.

The view of law as ideology, even in its radical variants, would not deny the presence of the rule of law in the liberal legal order; indeed, the rule of law is often invoked as a paradigmatic example of legal ideology. This is because, however, the rule of law is interpreted as a device that serves the interests of

the powerful; moreover, it is a device that dissembles itself. The rule of law, in its restraint on the exercise of governmental and judicial power, facilitates the aims of those with power of other kinds, particularly economic power. This is not a surprising argument, if one considers how right-wing thinkers like Frederick Hayek have lauded the rule of law for its essential role in buttressing the free market. Left wing and right wing thinkers are agreed, then, on the capitalist function of the rule of law.

For the left wing theorist of ideology, however, the rule of law also has ideological aspects that mean it serves capitalist purposes in more sinister ways. For in its restraint on political and legal power, the rule of law implies that these public forms of power are the only forms of power that exist, or at least the only ones that matter. Moreover, in assuring the subjects of the law that that law is applied with generality and certainty, the rule of law also implies that formal justice is the only relevant kind of justice; that equality before the law is identical to equality per se.

These claims about the rule of law and ideology are complex and need careful scrutiny. Does the rule of law necessarily involve manipulation on behalf of the capitalist order? Given its formal virtues, and its agnosticism on the content of law, the rule of law seems innocent of charges of a capitalist bias, or a bias of any kind. As Raz puts it, the rule of law's virtue is like the virtue of a sharp knife; it enables the law to fulfill its function, whatever the function might be. Moreover, it is hard to see how the rule of law itself is engaged in any project of deception. Generality in the law, for example, does not necessarily entail any particular commitments on how the economy or society should be organized; nor does it propagate falsity or error. Nonetheless, it is true that the proceduralism of the rule of law can be put to ideological purposes, to deflect social criticism and prevent radical change. And if enthusiasts of the rule of law place enough emphasis on procedural justice, this can reduce the likelihood that more substantive conceptions of justice will have success. Historically, societies governed by the rule of law have tended to be structured by capitalist markets, suggesting an affinity between the two sets of institutions. The rule of law can have an ideological effect even if it is not ideological in its essence.

5. Conclusion: Ideology and Justice

The idea that law is ideological is an important contribution to legal scholarship. First, it enables a more critical view of the law and its role, demystifying a set of vital social institutions. Second, it points to the importance of sociological and political factors in our understanding of the law. Legality is shaped and influenced by non-legal aspects of society, and law, in turn, has an impact on society and social change, not just in the obvious effects of particular judgments, but in the political culture that a legal system helps produce.

The ideology view risks, however, an unhelpful reductionism. Conceiving of law as ideological above all else can promote a crude and erroneous understanding of the relation between power and legality, where law serves only the interests of the powerful and where legal guarantees are mere shams. Moreover, this can license a cynicism about the law that is paradoxically contrary to the emancipatory aims of the radical politics that was the impetus for the critique of law as ideology in the first place. That is, radical critics risk dismissing altogether the possibility of legal recourse for remedying injustice.

Furthermore, the cynicism of the ideology view is in fact the fruits of a kind of utopianism about law, for it counters the bleak portrait of legal ideology manipulated on behalf of the powerful with an ideal society without ideology or law, where human beings' relations to each other and to reality are transparent and conflict-free. The 'end of ideology' thesis, advanced by Bell in a triumphalist spirit on behalf of liberal capitalism, but interestingly even more salient in Marxist ideals of communism, might be wrong in its assumption that human beings can transcend ideology. Indeed, the radical concept of ideology casts doubt on the likelihood that individuals' beliefs can provide an objective account of reality, untainted by distorted and self-justifying processes of inquiry.

How then, can the concept of ideology be deployed in legal scholarship? In fact, the more subtle critiques of ideology grasp the extent to which both liberation and manipulation can be embodied in the law. Recall the nuanced conception of Marx and Engels, where ideology gives an inverted image of reality, but a recognizable image nonetheless. This suggests that the ideals of legality are not a mere charade but are instantiated in the law, if only in a partial and incomplete form. The Marxist historian E.P. Thompson made this point in his argument for the universal value of the rule of law. Thompson contended that in order for law to function as ideology, it must proffer some genuine moral value.

To illustrate, consider how someone's cruelty might be masked by polite manners; this does not demonstrate that good manners have no worth. Legal ideology, too, might paper over injustice in ways that serve justice nonetheless. A functional argument about ideology, then, must concede the value of the phenomenon that serves ideological aims. Ideology cannot be devoid of emancipatory aspects altogether; if law trumpets justice, equality and freedom, then it must succeed in realizing these ideals, however imperfectly, in order for law to function as ideology. We can thus appreciate legal guarantees of a procedural kind for the genuine protection they offer the subjects of the law, whilst at the same time conceding the quietist politics that proceduralism might engender.

Moreover, understanding the ideological role of law need not undercut other conceptions of how law is to be defined or understood. This is particularly so if we recognize the unlikelihood of eliminating altogether ideological modes of understanding. A conception of law as having a moral source, or a source in a system's institutions, can be independent of a realistic appraisal of law's ideological function, or the ideological process in which laws are made. Both positivists and natural lawyers, so long as they do not insist that their conceptions of law are exhaustive of law's reality, can permit the influence of ideology, even in its more radical interpretations. Law can be ideology as well as other moral or institutional phenomena at the same time; indeed, law will probably not succeed as ideology unless it is multi-dimensional in just this way.

Antoine Le Grand

Antoine Le Grand (1629-1699) was a philosopher and catholic theologian who played an important role in propagating the Cartesian philosophy in England during the latter half of the seventeenth century. He was born in Douai, (at the time under rule by the Spanish Hapsburgs), and early in life was associated with an English community of Franciscans who had a college there. Le Grand became a Franciscan Recollect friar prior to leaving for England as a missionary in 1656. In England, he taught philosophy and theology, advocating Catholicism and eventually Cartesianism, the latter being as unpopular as the former was perilous. It is not clear how Le Grand came to Cartesianism, but the first evidence of his adoption of the new philosophy was in his *Institutio Philosophiae*, published in London in 1672. His early works show affinities to the philosophies of Seneca and Epicurus. He is noted for his polemical exchanges with Samuel Parker and John Sergeant, and for having given Descartes's work a Scholastic form so that it would be accepted in the schools.

1. Life and Writings

Le Grand lived in London for many years before retiring to Oxfordshire towards the close of his life in 1695. He was generally well-received at the University of Cambridge, perhaps owing to the influence of some leading Neo-Platonists at Cambridge such as John Smith, Henry More, and Ralph Cudworth, who were at least initially sympathetic to Descartes's ideas. John Smith, author of *Select Discourses* (1660), and the earliest recorded partisan of the Cartesian philosophy in England, was the first to introduce the study of Descartes to Cambridge. Henry More corresponded with Descartes, and was sympathetic until about 1665, when he launched the most vigorous attack on Cartesianism in the age, in his *Enchiridion Metaphysicum* (1671). Cudworth, like More although with less venom, objected to Descartes's

mechanistic account of the material world in his *The True Intellectual System of the Universe* (1678). It was Le Grand who debated and defended Descartes's philosophy to these English critics.

It is likely that Le Grand's edition of *Jacobi Rohaulti tractatus physicus* (1682) was the first of his Cartesian works accepted at Cambridge. This was a new edition, which included Le Grand's commentary, of Bonnet's 1672 Latin translation of Rohault's immensely popular tract of the Cartesian physics, *Traité de physique* (1671). In 1692, Samuel Clarke published his own Latin version of the text, which incorporates his and Le Grand's commentary in the form of footnotes. Clarke, though an adherent of Newton's physics, thought he could best propagate the new doctrine by publishing Rohault's text with suggestive notes directed at the necessity of modifying Cartesian theory. According to the biographical preface to Clarke's *Works*, at the time of his entrance to Cambridge in 1691, Rohault's *Traité* was the standard modern scientific text, and Newton's *Principia* (1687), had not yet been accepted: "The philosophy of Des Cartes was then the Established philosophy of that university, and the system of nature hardly allowed to be explained any otherwise than his principles … . The Great Sir Isaac Newton had indeed then published his Principia. But this book was but for the few." Eventually Clarke's translation of the *Traité*, which underwent four editions, became the new preferred Cambridge textbook, as the Cartesian physics gave way to that of Newton early in the eighteenth century.

At Oxford, Le Grand received a hostile reception. Samuel Parker aligned Hobbes's mechanism with that of Descartes, charging both with atheism. Parker's condemnations led to the banning of Descartes's philosophy at Oxford, quashing its public entrance at the University. Le Grand responded to Parker's charges of atheism in his *Apologia de Descartes* (1679), challenging Parker's criticisms with various proofs of God's existence. Another long-time, Oxford critic of Le Grand was the English secular priest and Aristotelian, John Sergeant. Sergeant, best known for his criticisms of Locke's philosophy, was also highly critical of the Cartesian philosophy. Le Grand responded to Sergeant's criticisms of the Cartesian criterion of truth in his *Dissertatio de ratione cognoscendi* … in 1679. A second major controversy occurred between the two authors late in Le Grand's life, this time over the nature of ideas. This dispute led Le Grand to write a series of short pieces, published later as *Several Smaller Pieces Against M. J. Sergeant* (1698). In response, Sergeant attacked the Cartesian idea of extension, to which the aging Le Grand never publicly responded. Le Grand died at the home of a wealthy farmer in Oxfordshire, where he had served as a tutor until his death in 1699.

Antoine Le Grand's most substantial work, *An Entire Body of Philosophy According to the Principles Of the Famous Renate des Cartes* (1694), is a Cartesian tract from beginning to end. It is based on a Latin text that underwent four editions before being translated into English by Richard Blome, and it includes corrections, alterations and additions by Le Grand himself. This work, as the title reveals, consists of three books. The first book, *The Institution*, is intended as a treatment of the general nature of things according to Descartes's principles; book two, *The History of Nature*, illustrates, by means of a great variety of reported experiments and examples, the operation of these first principles in nature. In this book, Le Grand applied the general Cartesian principles to his study of particular bodies and their qualities, showing how such principles can explain all natural phenomena. His extensive discussion includes bodies as various as the loadstone, plants, and insects. And finally, in his third book, *A Dissertation of the Want of Sense and Knowledge in Brute Animals*, he argued against the supposed link

of life and sense from Plato onwards, and after offering a brief survey of various hypotheses on the nature of soul by Aristotle, Gassendi, Fabri, and Descartes, he adopted Descartes's view. In the Preface, Le Grand wrote that, " … this whole work contains nothing else, but his [Descartes's] opinions, or what may clearly and distinctly be deduced from them."

2. Metaphysics

Le Grand defended the first principles of Descartes's philosophy with great fidelity. He held to Descartes's views that the essence of matter is extension; that the essence of mind is thought; that material substance and mental substance are essentially, and really distinct; that mind and body interact; that while humans have souls, brutes and other living things are mere machines; and that material things operate by means of moving parts according to the laws of motion. Le Grand did not make any substantial revisions to Cartesian metaphysics. However, he did make two important contributions: first, he attempted to clarify Descartes's account of motion which had direct consequences for the Cartesian account of matter, causation, and mind-body interaction; secondly, he extended the scope of Cartesian physics, treating such subjects as metals, plants, insects, animals, and the human body in detail.

Le Grand's contribution to the Cartesian account of motion may either be seen as an extension or a revision of Descartes's, sometimes ambiguous, treatment. Le Grand took seriously the claims that God is the total and efficient cause of motion in the universe, and that matter is entirely passive, and hence bodies are incapable of self-movement, or of moving other bodies. In his *Entire Body of Philosophy*, he argued that since a body may be in motion or at rest, motion must be a mode non-essential to matter. Moreover, given that matter itself is inert, it cannot be the source of the order and direction of motion. To provide order and direction, God laid down the laws of motion. Thus, motion itself as well as the orderly movement of bodies derives from God who acts as the effective principle. While the specific position, constitution, and configuration of the parts of a particular body determine how certain local motions are transferred, the source and ultimate direction of the motion itself is God. What this means for body-body interaction is that bodies function as secondary causes, directing local motions in virtue of the specific configurations of their parts. Bodies do not possess any causal power to produce or cease movement.

Le Grand's account of body-body interaction clears the way to explain mind-body interaction. In the same way as finite bodies, God functions as the effective principle of finite minds, providing the ultimate source of change: " … there is nothing, besides motion, which can strike the organs of the senses, or affect the mind itself." (1694, p. 284) Although mind and matter are substances sharing no common properties, it is in virtue of God acting as the effective principle that mind and body interact. This kind of interaction is no more or no less problematic than the interaction of two physical bodies. There was no real problem of interaction for Le Grand, since he believed that it was not the substances per se that acted on one another but in all cases God alone provided the motive force in the universe. Although things by their nature respond to this motive force in an orderly way, i.e., according to the laws of nature, the fact that they exist as they do and that they interact is a fact completely dependent on God's will. God's power is expressed as local motions in bodies and as passions/thoughts in minds. In short, it is in virtue of God, their effective principle, that a mind and body, or a body and body, or even a mind and mind, are said to

interact.

Le Grand described the mind-body union in terms directly borrowed from Descartes. However, Le Grand attempted to explicate further than did Descartes the nature of the mind-body union. According to Le Grand, there are three kinds of union, each possessing its own principle which effects that union: the first is that of two minds whose principle of union is love; the second is that of two physical bodies whose principle of union is local presence; and the third is that of the mind and body whose principle of union is actual dependence. Just as two physical bodies are joined by physical contact, and as two minds are joined by love, the mind and body are joined by a mutually dependent activity. So long as the body actually receives its specific motions dependently on the soul, and the soul actually receives its local motions (passions) dependently on the body, the spirit and the body are joined. Although there can be no mode common to mind and matter, there is this mutual action. While there is no mode shared by two different substances, there is a similitude and relation that exists between mind and body: "This similitude and relation we have formerly affirmed to consist in action and passion." (1694, p. 325) In other words, just as the body is capable of receiving and transmitting local motions since motion is a mode of matter, the mind is capable of varying passions since passions are a mode of the mind. It is by the mutual commerce of such motions and passions that the mind and body are said to be united. The mutual activity said to occur between the mind and the body is a property which follows only from the union of mind and body and cannot proceed from either alone, "And the truth is, since neither body can think, nor mind be capable of dimension, there can be no mode common to mind and body, except a mutual acting of each upon each, from which alone the properties of both can follow." (1694, p. 325)

Le Grand's extensions to Descartes's physics included phenomena now classified as metallurgy, entomology, botany, biology, physiology, medicine, and psychiatry. Part II of the *Entire Body of Philosophy*, entitled *The History of Nature*, catalogues and critically discusses the latest experiments of his time, as well as the theories of the ancients and moderns. Prominent in his discussions is the importance of secondary causes in nature (both exemplary and secondary efficient causes), and the need for experiments, not just as tools of confirmation, but also as a means of discovering the true nature of things. This was due to his application of mechanism to explain not only the behavior of material bodies but also the entire institution of nature. Le Grand believed that God laid down the laws of nature and the principles of being by acting as the primary efficient cause, and that the operation of these laws and principles manifested themselves in nature in the form of secondary causes and effects. Although the laws and their specific mechanisms of operation are not visible, secondary causes and their effects are. These causes and effects then are known by experience and are the starting point of all science, which is characterized by reasoning from effects (observed in nature) to causes (first principles discerned by reason).

3. Epistemology

Le Grand's account of sensations and ideas is orthodox Cartesianism. Sensory impressions are what mediate the external object and our mind's idea of it, and they consist in nothing more than the immediate motions of the sensory organs in the body. Such motions are produced by a natural necessity and they

share no similarity or affinity with the particular objects that cause them. Like Descartes, Le Grand used the example of the sword wounding the body to illustrate the non-resemblance or dissimilitude of the relations between external objects and sensations, and sensations and ideas. (1694, p. 327) The sword that produces pain in us is nothing like our sensation or idea of pain, nor is our idea of pain anything like our sensation of pain. Yet, we maintain that there is a causal and representational relation between the sword and the idea it produces. In addition, Legrand like Descartes made a clear distinction between sensory impressions, which are particular, quantifiable motions, and ideas, which are representational or propositional in character. Given that sensations are non-resembling and non-representational (they are mere patterns of local motions) it follows that ideas, which are essentially representational, could not be derived from them.

From the lack of any form of similitude or affinity between object/sensation, and sensation/idea, it follows that there is no such relation which holds between an idea and an external (material) object. From this lack of similitude, Le Grand concluded that adventitious ideas (coming from material objects outside us) must be innate or inbred in the mind. For, if the external object is not like the idea we form of it, then the only explanation remaining is that the mind is responsible for it. Likewise, fictitious ideas, like sirens and chimeras, have no exemplar outside the mind and so must be formed according to forms natural to the human mind. And finally, common notions such as substance, truth, goodness, equity, and God, as well as axioms such as the same thing cannot be and not be, are innate, that is, they proceed from the mind alone, since all corporeal motions are particular but these notions are universal. The sense in which they are innate differs from adventitious and fictitious ideas; innate ideas do not proceed from the senses or the imagination but "are congenite and inbred with the said mind, from their original." (1694, p. 328) By this Le Grand meant that the mind or thought itself, not any of its faculties such as sense or intellection, is the principle or original of such ideas. These ideas are formed in the mind by the mind and from the mind.

Thus as Descartes held, there are three kinds of ideas (adventitious, fictitious, and innate), which are distinguished by their differing sources as well as the way in which they are inbred in the mind. Adventitious ideas proceed from the senses, fictitious ideas proceed from the imagination and the intellect, and innate ideas proceed from thought itself, which acts as their ground or original. Nonetheless, all ideas, regardless of their source or origin, depend on the mind in some essential way for their form. But this gives rise to the problem of explaining how ideas can be said to represent, if they in no way resemble their objects. This problem is especially acute for Cartesians who held that there is a modal difference between what is found at the level of sensory perception and intellection, such that impressions cannot contain any of the properties found at the level of ideas. What arrives at our faculty of thinking from the senses is not ideas such as we form them in our thought, as the scholastic empiricists held, but rather only various particular motions emitted by external objects. (1694, p. 328)

Le Grand's solution to the problem of how ideas represent their objects employed the notion of substitution or ‘supplying a stead’ -- wherein the cause (the object) contains all the properties found in the effect (the idea) not actually but in virtue of its ability to supply the substitute properties or proxies. And a relation, according to Le Grand, "…is nothing else but a mode of our understanding, comparing one thing with others, because of some properties or acts that are found in them." (1694, p. 17) Descartes

himself never cashed out the notion of representation in terms of substitution, although he came close to suggesting it in the French version of the Third Meditation, in which he claimed that such things as extension, shape, position and movement may be contained in him eminently, "…and as it were the garments under which corporeal substance appears to us." (1985-91b, fn.1, p. 31) One could conceivably interpret this to mean that the garments of corporeal substance, namely extension, shape, position and movement are the garments supplied by the mind as the forms or the conceptions under which the mind grasps material things. Although the mind itself is not extended, shaped, locally positioned or moved, it dresses material substance in these properties in order to perceive particular material things. But there is no suggestion in Descartes regarding how the dressing is related to the material object grasped. Le Grand's notion of substitution was intended as an explication of this relation, and is his contribution to the Cartesian dialectic on ideas.

Le Grand was one of the few Cartesians to defend Descartes's doctrine of the creation of essences and eternal truths. The thesis is that God is the efficient cause of all things, both actual and possible, including all the truths we call eternal, "In like manner as a king is the maker of all laws in his kingdom. For all these truths are inborn in us from him; as a king also would have them so in his subjects, if he had power enough to write his laws in their hearts." (1694, p. 63) The main worry that critics, like Malebranche, had of this doctrine was that it would remove any necessary foundation for the propositions of science and theology, making them contingent and uncertain. To answer this worry, Le Grand added that there is one important difference between kings and God in the way they set down their laws, "A king can change his laws because his will is changeable, but God's will is unchangeable, for it is His perfection to be invariable in manner." (1694, p. 63) In this way, Le Grand attempted to account for the dependence of all things on God's will, while at the same time accounting for the immutable foundation of the truths of natural philosophy.

Whereas the creation of true and immutable natures was the work of God's freewill (not dictated according to his Wisdom, as Malebranche and other critics held), once created, they were necessary. In order to tie this necessity to the immutability of God's will without limiting God in any way, Le Grand drew on a Scholastic distinction between antecedent and consequent necessity. He argued that true and immutable natures, such as mathematical truths, only possessed a consequent necessity. God did not will that 6+4=10 because he saw it could not be otherwise, but in virtue of his free will, 6+4 [necessarily] = 10; therefore it could not be otherwise. As Descartes put this same point, "And even if God has willed that some truths should be necessary, this does not mean that he willed them necessarily; for it is one thing to will that they be necessary, and quite another to will this necessarily, or to be necessitated to will it." [1985-91c, p. 235]. For nothing outside of God, not even the eternal truths or immutable essences, necessitate that God act in one way or another, but rather, they are themselves eternal and immutable in virtue of the fact that God, whose existence is necessary and immutable, willed them in their essence and existence. Eternal truths and immutable essences are necessary only in that they presuppose and are consequent to the act of God who caused them.

Echoing Descartes in part VI of the *Discourse on Method*, Le Grand held that God implanted certain simple, true, and immutable ideas in our minds so that we could have a science of nature; yet, He also created a nature whose power is so ample and vast that only observation can close the gap between the

two. Thus, while Le Grand remains essentially a rationalist in his claim that knowledge of immutable essences, laws and truths remains the autonomous domain of reason, which is independent of the appearances of the senses, it is a rationalism tempered by his view that truths and laws are dependent on the will of God, and hence, are in some sense contingent. This dependence means that truth must be sought after in the effects of nature, and not in something independent of those effects, and that secondary causes, although dependent both on God's will and on the primary truths of nature, have a genuine role in causal explanation. In other words, our search for truth is in the specific operations of things, and even though our understanding of these truths is importantly independent of these specific operations, our discovery of them is not.

4. Ethics

Le Grand's early ethical and political writings are not Cartesian. In *Le Sage des Stoïques, ou l'Homme sans Passions, Selon les Sentiments de Sénèque* (1662), later translated and published as *Man Without Passions* (1675), he expounds the Stoical doctrines of Seneca, for which the goal of the moral person is to expunge the passions. He later rejected this view of the passions and argued the Cartesian view that the passions ought to be trained (not expunged) in the moral life. Le Grand also wrote a curious political treatise, *Scydromedia* (1669), which is a semi-fictional, utopian work describing his vision of the ideal state.

There is nothing innovative in Le Grand's moral theory, yet his discussions are rich with references to ancient and contemporary theories. He borrows from the ancient Atomists, the Stoics, the Scholastics, and the "Moralists" of his time, and frames it, where possible, in Cartesian terms. Le Grand acknowledges that Descartes himself wrote little on ethics, but he argues that Descartes's treatment of the soul and the passions provides a solid foundation for the treatment of moral matters. According to Le Grand, the object of ethics is right reason, its end is the perfection of man, and it is an active not a speculative science. An example of his reconciling project can be seen in Book I, Part X of his *Entire Body of Philosophy* (1694), where Le Grand attempted to reconcile the doctrines of Seneca and Epicurus on the role of pleasure in the virtuous life, by drawing on Descartes's theory of the passions. (1694, p. 347) He argues that pleasure has a role to play in the moral life, since virtue depends on freewill (as the Stoics held) and pleasure derives from the satisfaction of the mind in possessing the good (as Epicurus held). What Descartes's theory provided was an explanation of how pleasure (a passion) could aid the will in choosing the right course of action, while maintaining the voluntary nature of the will and virtue.

Le Grand, although not an innovator, is worthy of study for his contribution to the development of Cartesianism in the latter half of the seventeenth century. No less important is the fact that he spent most of his life in England, where his contact with members of the Royal Society and the universities of Cambridge and Oxford had a lasting impact on the reception of Descartes's ideas in England, Germany, and France.

Godfrey of Fontaines

Godfrey of Fontaines was one of the major philosopher-theologians to serve as Regent Master at the University of Paris in the final quarter of the thirteenth century, along with Henry of Ghent and Giles of Rome. After completing philosophical studies in the Faculty of Arts and beginning to study theology probably by August, 1274, he became Regent Master in Theology in 1285 and retained this position until 1303/1304. His greatest contributions to philosophy were in the area of metaphysics. He was positively influenced by Thomas Aquinas, but differed with him on various major points, and also seems to have been influenced by the Arts Master, Siger of Brabant. His might well be described as a metaphysics of act and potency, since he often turns to this in seeking to resolve metaphysical problems such as, for instance, the relationship between essence and existence and between possible and actual being, the distinction between substance and accidents and between the soul and its powers, the causes of intellection and volition, or the nature of prime matter and its relationship to substantial form. Overall his philosophical thought and especially his metaphysics is somewhat more Aristotelian and less influenced by Neoplatonism than that of many of his contemporaries, including Aquinas.

1. Life and Writings

Godfrey of Fontaines was born in present day Belgium in the principality of Liège, very likely at the chateau of the noble family of which he was a member, at Fontaines-les Hozémont, probably shortly before 1250. This approximate date can be inferred from the fact that he conducted his first quodlibetal dispute as a Master of Theology at Paris in 1285, and that one could not become a Master in this faculty before reaching the age of 35. While nothing is known with certainty about his life prior to his arrival at Paris, he must have pursued philosophical studies there in the Faculty of Arts in the early 1270s. University statutes required one to spend at least eight years in studying theology before becoming a Master, and it is also known that he was inscribed at the Sorbonne before August 15, 1274. Hence his theological studies should have begun by that date (De Wulf, 1904, 3-16; Wippel, 1981, xv-xviii).

Evidently a great lover of books, among the surviving 37 manuscripts Godfrey left to the Sorbonne is a valuable "Student Notebook" (Paris: Bibl. Nat. lat. 16.297) which he himself compiled during his student days at Paris, and into which he entered many writings in his own hand. While not completed until ca. 1280 rather than by 1274 or earlier as previously proposed, it reflects his interests in the 1270s and includes works by Thomas Aquinas, Siger of Brabant, Boethius of Dacia, other anonymous Questions on various works of Aristotle which are clearly by some Master(s) of Arts of the time, still others by Giles of Rome, some extracts from Albert the Great and from Henry of Ghent, as well as some other purely theological writings (Wippel, 2001, 360-67; Duin, 1959). His interest in the writings of Radical Aristotelian Arts Masters at Paris in the 1260s and 1270s is also indicated by other works of Arts Masters included in additional manuscripts in his library (Bibl. Nat. lat. 15.819, 16.096). Also noteworthy is the inclusion in his Student Notebook of one of the oldest and most reliable copies of Thomas Aquinas's controversial *De aeternitate mundi*, which itself dates from 1270.

Godfrey continued to teach as a Master of Theology at the University until ca. 1303/1304 when he conducted his fifteenth and last Quodlibetal Disputation. He may have been away from Paris for some more extended periods after completing Quodlibet XIV ca. 1298-1299. It is known that he maintained close connections with Liège during his career at Paris and, indeed, that he served as Canon of Liège. He also served as Canon of Tournai and as Provost of San Severin at Cologne, and was elected Bishop of Tournai in 1300 but renounced his rights to the See when the election was contested. The year of his death is probably 1306 or 1309, but the day is known, i.e., October 29.

Godfrey selected the quodlibetal disputation as his major vehicle for publication. These solemn disputations were conducted twice during the academic year, i.e., before Christmas and before Easter. They were open to all members of the learned public and questions could be put to the presiding Master by anyone in attendance. During the first day's disputation, preliminary answers would be given to these many and disparate questions. On the following day or at least on some following day, the Master, having in the meantime imposed some logical organizing plan upon the various questions, would return for another session where he would present his definitive response or "determination" for each of them.

Subsequently he would prepare this version for publication and, when it was completed, would submit it to the University Bookseller. Masters were not required to conduct these open disputations and since they were regarded as onerous, not all did. Godfrey's 15 Quodlibets have all been edited, although only *reportationes* of the first four remain, i.e., copies taken down by an auditor. Brief versions (*abbreviationes)* of Quodlibets III and IV have also been edited. As a Master of theology Godfrey also conducted ordinary Disputed Questions, and some of these have been preserved.

2. Subject of Metaphysics

Godfrey was surely familiar with the controversy concerning whether one should with Avicenna stress the nonparticular and therefore the universal character of being as being and hence make this the subject of metaphysics or rather with Averroes emphasize it as the science which has the highest kind of being, the divine, as its subject. On this Godfrey clearly agrees with Avicenna, even though he devotes little explicit attention to the controversy itself. Thus in Quodlibet X, q. 11 he holds that being as being is the object (or subject) of metaphysics (PB 4.349), and in Quodlibet VI, q. 6 that the concept of being is first and simplest because it enters into every other concept (PB 3.137). Therefore it is also the most general concept or, one may say, transcendental. At times Godfrey also describes the object of the intellect as being as being (Quodlibet II, q. 8). He denies that God is the subject of metaphysics, even though God is the first and primary being and must be studied within metaphysics (Quodlibet I, q. 5). He distinguishes a metaphysical study of God, which he says may be described as a kind of theology, from the theology that is based on Sacred Scripture. This does not have being as being as its subject, but God himself (Quodlibet IX, q. 20; Wippel, 1981, 3-15).

3. Division of Being

In opposition to Henry of Ghent's division of real being into essential being (*esse essentiae*) and existential being (*esse existentiae*), in Quodlibet VIII, q. 3 Godfrey proposes his own division. Being (*esse*) may be divided into being in the mind ("cognitive" being) which is a lesser or diminished being, and real being, i.e., being outside the mind or knower. Real being is subdivided into real being in potency and real being in act. A thing possesses real being in potency insofar as it has being by reason of its cause or causes. It has real being in act insofar as it is realized in its own nature in completed or perfected form. A thing may have real being in potency either by reason of its intrinsic cause (e.g., if matter preexists which may enter into the thing's constitution), or by reason of an extrinsic cause (e.g., if an agent preexists which can produce it). Godfrey illustrates this with the example of a rose that does not yet actually exist. Prior to the creation of the world and hence of matter it possessed real being in potency only by reason of God, its extrinsic cause. After creation it possessed real being in potency by reason of preexisting matter as well, an intrinsic cause. And now it may also possess real potential being by reason of some created extrinsic cause (or causes). Both before and after the world's creation it enjoys cognitive being insofar as it was and is known by the divine mind (PB 4.38-40; Wippel, 1981, 15-17).

4. Analogy of Being

In describing being as being as the object of the intellect in Quodlibet II, q. 8, Godfrey also states that being is taken analogically and not univocally. It is affirmed first and foremost of substance, especially of first substance, and of everything else as related to substance. Hence both substance and accident are included under this analogous notion of being and this single object of the intellect (PB 2.135-36; Wippel, 1981, 19-24). In Quodlibet III, q. 1 he attempts to establish the analogical character of being by arguing at some length that it cannot be either univocal or purely equivocal. Central to his rejection of univocity of being is his denial that it is a supreme genus. It must apply not only to the generic and specific aspects in which different things share, but also to the differences, including the individual differences between them (PB 2.162-63). In Quodlibet XV, q. 3, while responding to an objection perhaps taken from Meister Eckhart's Parisian Disputed Question 1, he maintains that, if being is applied to accidents insofar as they are related to substance in some way, this does not mean that being is not intrinsically present in accidents. So, too, when it is applied to creatures viewed as effects and to God their cause, it applies intrinsically to God. There is an analogy and proportion in reality between these different instantiations of being and corresponding to this, there is analogy in meaning as well. It is this that is grasped by the analogous concept of being (PB 14.18-20; Wippel, 2001, 381-82).

5. Transcendentals

In Quodlibet III, q. 1 Godfrey identifies the one, the true, and the good as properties of being that are really identical and convertible with it, and hence as transcendental characteristics of being. These properties are not really distinct from being itself (PB 2.163-64). In Quodlibet VI, q. 16 he distinguishes between the one or the kind of unity that serves as a principle for number and which is based on discrete quantity (numerical unity in the strict sense), and the kind that is convertible with being. While the former is restricted to corporeal being, the latter applies to every subsisting substance and to every accident that exists in such a substance. Hence it alone is transcendental (PB 3.256-58). Regarding the true, in Quodlibet VI, q. 6 Godfrey indicates that truth adds nothing real to being but only a (conceptual) relationship to mind or intellect. To assign this kind of truth to a thing is simply to acknowledge that it can be grasped by intellect or that it is intelligible. Consequently, Godfrey holds that truth is present in being virtually insofar as it has the capacity (*virtus*) to produce truth in the intellect. But he favors the view that when taken formally truth resides in the intellect (PB 3.137-41; Wippel, 1981, 25-34). Hence here he is recognizing the distinction later referred to as that between ontological truth and logical truth.

6. Essence and Existence

Already during Godfrey's student days in Arts and in Theology at Paris there was considerable discussion concerning the exact relationship between essence and existence in finite or created beings. Closely associated with the metaphysical thought of Aquinas was the view that in all finite beings there is a real, i.e., not merely a conceptual or mind-dependent distinction and composition of an essence principle and

an act of existing (*esse*) or existence principle. Already in the 1270s Giles of Rome was developing his own theory of real distinction between essence and existence, and was soon engaged in ongoing controversy with Henry of Ghent. At times Giles referred to essence and existence as distinct "things" (*res*) and, while he denied that either could exist in separation from the other or that existence is an essence, his terminology left its mark on the theory and open to such misinterpretations; for it invited critics to view existence or the act of being as an entity rather than as a principle of an existing entity, as Aquinas had envisioned it. While Henry of Ghent rejected any real distinction between essence and existence, he defended something more than a merely conceptual distinction between them, namely a new and third type that would fall between the real distinction and the merely conceptual, an "intentional" distinction (Wippel, 1981, 40-45).

Godfrey briefly refers to this issue in Quodlibet II, q. 2, while attempting to determine whether the essence of a creature is indifferent to existence and nonexistence. He comments that either essence is really identical with existence and differs from it (1) only conceptually or (2) intentionally, or else (3) existence is a distinct thing, i.e., the act of the essence and really distinct from it (PB 2.60). In Quodlibet IV, q. 2, he was asked to determine whether to hold that predicamental things are eternal by reason of their quiddity is also to hold that the world is eternal. In preparing his response he presents in greater detail these three different views on the relationship between essence and existence (*esse*). According to some they are really distinct from one another and enter into real composition with one another. But one is not separable from the other so as to be able to exist apart from it. Consequently, if a thing lacks or loses its existential being, it also lacks or loses its essential being. According to a second view they are really identical, but differ intentionally. Hence when a thing loses its existential being, its essence cannot be said to exist; but it does retain its true predicamental or essential being (*esse essentiae*). Finally, a third position, which Godfrey himself embraces, maintains that they are really identical and differ only conceptually. They do not enter into composition with one another. Therefore, to the extent that something enjoys essential being, to that same degree it enjoys actual existence. And, adds Godfrey, whatever is understood of one is also understood of the other (PB 2.235).

In Quodlibet III, q. 1, dating from 1286, Godfrey considers the argumentation offered for each of these positions. First he presents the theory that distinguishes really between essence and existence in language that reflects the terminology of Giles of Rome. Thus he refers to existence both as "something" (*aliquid*) and as a "thing" (*res*) that is added to essence. He then presents a number of arguments in support of this view which seem to be taken from Giles, especially from his *Quaestiones disputatae de esse et essentia*, q. 11. One of these is reminiscent of the first part of Aquinas's much discussed reasoning in *De ente et essentia*, c. 4, which begins from the fact that one can understand what something is without knowing whether it actually exists. However, Giles's presentation (and Godfrey's repetition) of the argument makes a stronger claim. One can understand what something is and also know that it does not exist. But because nothing can be understood with the opposite of itself, essence and existence must be really distinct. After presenting a series of arguments against this theory and refuting the arguments he had initially offered in support of it, Godfrey resolutely rejects any real distinction between essence and existence. For him they are identical, and differ only in the way they signify, just as the concrete noun "a being" (*ens*), the abstract noun "essence" (*essentia*), and the verb "to be" or "to exist" (*esse*) differ in their mode of signifying, but designate one and the same reality (PB 3.304 [brief version]; Wippel, 1981, 45-

66).

In presenting Henry's theory of intentional distinction Godfrey traces this back in large measure to what he regards as an incorrect interpretation of Avicenna's notion of nature or essence when it is considered simply in itself or "absolutely" rather than as existing in the mind or in an individual entity. As Godfrey explains in his later Quodlibet VIII, q. 3, according to Henry's position real being is divided into essential being (*esse essentiae*) and existential being (*esse existentiae*). A thing possesses essential being from eternity insofar as it corresponds to its appropriate exemplar idea within the divine intellect. Because of this it is a true or real quiddity or essence from eternity and falls into its appropriate predicament even though it is not an actual existent. Existing entities receive actual existence only in the course of time when the divine will intervenes to cause this. Within an actually existing being, therefore, its essence and existence are not really distinct. But Henry denies that they are identical. They are "intentionally" distinct (Wippel, 1981, 67-79; Marrone, 2001, 39-52; Porro, 1996, 211-53). Godfrey rejects Henry's new and intermediary kind of distinction out of hand. A distinction must either be real or purely conceptual. Accordingly, in Quodlibet III, q. 1 he argues at length against Henry's application of the intentional distinction to essence and existence Wippel, 1981, 85-88).

As already noted, for Godfrey essence and existence are really identical and only differ conceptually. Whatever is true of essence is true of existence, and vice versa. It is not necessary to posit two really distinct or even two intentionally distinct principles to account for the fact that one may be aware of something as a possible existent when it does not actually exist. It is enough to distinguish between potential being and actual being. If something is in potency in terms of its essence, it is in potency in terms of its existence. And if it is actual in terms of its essence, it is actual in terms of its existence.

Godfrey proposes a different kind of act-potency "composition" in order to meet one argument in support of real distinction between essence and existence. If, as Aquinas, Giles, and Godfrey all hold, the angels of Christianity are purely spiritual and not composed of (spiritual) matter and form, then it seems that they must be composed of essence and existence. Otherwise they would be perfectly simple and equal to God. Godfrey responds that one and the same being, even if purely spiritual, may be regarded as actual insofar as it exists, but as potential insofar as it falls short of the actuality enjoyed by a higher being and, above all, by the First Being, God. He quotes Proposition 2 from Proclus's *Elementatio theologica*: "What participates in the One is both One and not-One." As Godfrey reads this, anything that is different from the One can fall short of it only by approaching (*accessus*) the not-one. Hence it is simply by reason of the fact that such a being recedes from the One that it is not the One itself. In this way more perfect beings such as angels are distinct from the One, or God, without being composed either of matter and form or of essence and existence. Nonetheless, actuality and potentiality are present in them because they possess a certain intermediary nature and hence are likened or "assimilated" to something higher and more actual, and to something lower and more potential. Therefore they are "composed" of potency and act, not really, but conceptually. This composition is not merely imaginary. It applies to such entities by their being related to something higher and to something lower (Quodlibet III, qq. 1, 3; Quodlibet VII, q. 7; Wippel, 1981, 90-97).

Godfrey's library contains two likely sources for this theory, first a rudimentary version found in the

abbreviated text of Siger of Brabant's *Quaestiones in Metaphysicam* included in Godfrey's Student Notebook, and second, an anonymous set of questions on the *Posterior Analytics* contained in the manuscript Bibl. Nat. lat. 16.096. While Godfrey literally borrows certain parts of his theory from the second text, he does not follow this anonymous Radical Aristotelian Arts Master when he goes on to argue that separate entities do not depend upon God as their efficient cause, but only as their final cause (Wippel, 1984), 231-44.

7. Philosophical Knowledge of God's Existence

According to Godfrey, insofar as a natural knowledge of God is accessible to human reason, it belongs more properly to metaphysics than does knowledge of any other being. And he clearly holds that God's existence can be established by philosophical reasoning. But Avicenna and Averroes had differed concerning whether it belongs to natural philosophy (physics) or to metaphysics to demonstrate this conclusion. Avicenna had maintained that this task pertains to metaphysics and only to metaphysics, whereas Averroes had defended the opposite position that only physics can demonstrate the existence of God, the First Mover (Wippel, 1981, 102-3). As will be seen more fully in the following section, Godfrey defends something of a compromise position. In Quodlibet XI, q. 1 he mentions that the metaphysician's consideration of God in himself is more perfect than that of the natural philosopher, who simply views him as the First Mover of the first mobile being, i.e., the outermost heavenly sphere. But, Godfrey adds, by reason of all that God is in himself, he is also the First Mover (PB 5.3). In Quodlibet V, q. 10 he writes that one can know by reasoning from natural things that God is the first being which depends on nothing whatsoever and upon which everything else depends and, therefore, that he is the causal and productive principle of all other things (PB 3.41; Wippel, 1981, 105). And in Quodlibet IX, q. 20, he refers to different things that natural reason can know in metaphysics with certainty about God—that because he is the first being he is simple; that he is being in actuality; that he is an intellectual being, etc. (PB 4.288).

8. Quidditative Knowledge of God and the Divine Attributes

In Quodlibet VII, q. 11 Godfrey considers the view of some, presumably Thomas Aquinas, who say that in this life we can know that God is, but not what he is. Godfrey makes a clear but implicit reference to ST I, q. 3, a. 4 where Thomas writes that even when we recognize that God is, the "is" which we understand is not the act of being whereby God subsists in himself, but only that indicating that the proposition "that he is" is true (PB 3.383).

Godfrey finds this too restrictive. And so after offering a detailed explanation of the different ways in which one can know of something "what it is" and "that it is," he writes that just as in knowing material things we move from more confused to less confused knowledge, so it is in the case of our natural knowledge of God. Just as we find that some things are the principal causes of others, and some are

governed by others, so we impose the name "God" to signify something in the universe which is the one first cause of everything else and than which nothing greater can be thought. But such nominal knowledge is not enough to prove that what we express by the name "God" exists in reality or "that he is." Next we may follow Aristotle's procedure in *Physics* VII where by eliminating recourse to an infinite regress of moved movers he concludes that one First Mover or God exists. And from the continuous motion of the first mobile sphere Aristotle shows in *Physics* VIII that God is perpetual and pure act. This tells us that God is in reality, but not what he is in any real sense. In the *Metaphysics* (Bk XII), continues Godfrey, Aristotle accepts the knowledge "that God is" as proved in the *Physics* and now proceeds to show that certain perfections are present in God to the preeminent degree. According to Godfrey, Aristotle uses these perfections as quasi-differences and thereby progresses from knowledge "that God is" to knowledge "what he is" by passing from a confused and quasi-generic knowledge to a more determined and quasi-specific knowledge. And so, too, proposes Godfrey, we may reason, for instance, first by knowing him as a substance, then as an incorporeal substance, then as a living and intelligent incorporeal substance. He acknowledges that God does not really fall into any genus or species. Nonetheless, he maintains against Aquinas that we can know "what God is" in some real sense, even though he recognizes that in this life such knowledge will always be imperfect (PB 3.384-86; Wippel, 1981, 108-15).

Consistent with the above, Godfrey defends the presence of a plurality of attributes in God even though, because of the divine simplicity, these are only conceptually distinct from the divine essence and from one another. In Quodlibet VII, q. 1 he distinguishes two ways in which the term "attribute" may be taken. It may be used to signify a divine perfection in the sense that some perfection in a creature which does not imply any imperfection in and of itself, in other words a pure perfection, is assigned to God to an eminent degree. Or it may be taken as signifying a pure perfection which is realized in God as a "quasi-quality" which perfects the divine substance in a "quasi-accidental" fashion. Godfrey comments that it is in this second sense that attributes are usually applied to God, even though this is not intended to imply any real distinction or composition of substance and attribute in him. When taken in this second sense, Godfrey holds that there are many such quasi-qualities which perfect God in this quasi-accidental way, and therefore, many divine attributes. They are assigned to God in preeminent fashion because of his infinite perfection (PB 3.265).

In this same question Godfrey was asked to resolve a still more fundamental issue. Because of God's absolute simplicity, divine attributes signify perfections that are really identical with the divine essence and with one another. The conceptual distinction between them can only arise from an intellect's consideration. But what is the ultimate foundation for this conceptual distinction? Does it arise from a consideration of God simply as he is in himself, or does it only result from some reference to really distinct realizations of these perfections in creatures? Godfrey replies that if one takes an attribute in the first sense as implying that every pure perfection present in creatures is to be assigned to God to an infinite degree, the answer is clear. The intellect, especially a created intellect, can arrive at such a conceptual distinction of divine attributes only by reasoning from the really distinct instantiations of such perfections in creatures (PB 3.267-70; Wippel, 1981, 116-18). But what about the divine intellect? Godfrey then refers to and rejects the view of Henry of Ghent, according to whom attributes, when taken in the second sense, can be recognized as distinct and as multiple by God himself insofar as he views

himself directly and without any reference to creatures. Against Henry, Godfrey maintains that not even God himself can be aware of this conceptual distinction between the divine attributes without referring to other beings in which these perfections are present in really distinct fashion. To hold otherwise would be to introduce too much distinction and diversity into the divine essence itself and would thereby compromise the divine simplicity (PB 3.267-73; Wippel, 1981, 118-23; Maurer, 1999, 192-200).

9. Eternity of the World

Together with his Christian contemporaries, Godfrey believed that the world began to be. But much debated was the question whether natural reason can prove this, or whether it can be held solely on the grounds of religious faith. Probably best known for holding that it cannot be demonstrated that the world began to be was Thomas Aquinas who in his *De aeternitate mundi* went a step beyond his earlier writings and maintained not only this but also that an eternally created world is possible (Wippel, 1984, 203-14). Bonaventure had presented a series of arguments to prove that the world began to be, and many others strongly defended this position, including Henry of Ghent (Dales, 1990; Wippel, 1981, 153-58). Thus it is not surprising that in his Quodlibet II, q. 3 of Lent, 1286, Godfrey was asked to determine whether the world or any creature could be or exist from eternity.

Godfrey develops his position in conscious opposition to Henry of Ghent, and with a considerable but unacknowledged dependency on Aquinas's *De aeternitate mundi* which, as noted above, was contained in his Student Notebook. But after he has, with Aquinas, shown that there is no contradiction in holding that something can be created and still have begun to be, Godfrey considers certain objections against this position. One of these objections clearly gives him pause. If the world had been created from eternity, on every given day extending backward into a beginningless past God could have created some material object such as a stone. But if that had happened, an actual infinity of stones would now exist and God could unite all of them into one infinite body. But an infinite body is an impossibility, and so too is an infinity of simultaneously existing finite bodies and, therefore, so is an eternally created world (PB 2.68-69, 76; Wippel, 1981, 160-63).

Godfrey comments that this objection can also be formulated more forcefully in terms of human souls, i.e., the actual infinity of human souls that would have resulted from an eternal world eternally populated by human beings with immortal souls. Aquinas had considered this form of the objection in his *De aeternitate mundi*, and had noted that it has not yet been demonstrated that God could not produce an actual infinity of spiritual beings. Godfrey does not adopt this solution, presumably because he is convinced that an actual infinity of entities whether spiritual or material is impossible. Instead he proposes as a possible alternative an eternally populated world involving the transmigration of a finite number of souls to an infinity of bodies, and ordered only to their natural perfection. But because this world seems to be intended primarily for human beings destined to enjoy eternal happiness in soul and body, Godfrey grants that it may be argued with probability that this world could not have been created from eternity under the present dispensation by God's ordained power. But, he also remarks, this does not prove that no creature or no world could have been eternally created. He concludes that it cannot be demonstrated either that an eternal world is not possible, or that it is possible. Either side may be

regarded as probable, and neither is to be rejected as theologically erroneous (PB 2.79-80; Wippel, 1981, 167-68).

10. Substance, Accidents, Human Action

In Quodlibet XIV, q. 5 Godfrey contrasts mental being with extramental being and then divides the latter into being *per se* and being *per accidens*. Being *per se* is divided into substance and the nine genera of accidents. The latter may be regarded as real modes of substance or of being in the unqualified sense (*ens simpliciter*). As Godfrey indicates elsewhere, a substance enjoys a separate being or exists in itself, while it is of the nature of an accident to be ordered to and to exist in something else. An accident is not so much a being as "of a being" (PB 5.427) For practical purposes Godfrey accepts the number of predicaments as ten, but indicates that determination of their precise number is a matter of probability rather than certainty (Wippel, 1981, 174-75). For Godfrey substance and accident are related as potency and act since substance serves as a subject for its accidents. Because of this he denies that any substance can be the efficient cause of the accidents that inhere in it, for it would then be in act with respect to them (as their efficient cause) and in potency (as receiving them) at one and the same time. He would always insist that nothing can be in act and in potency at one and the same time with respect to the same thing for this would be to assign being and nonbeing to it simultaneously. He also holds against many of his contemporaries that the powers of the soul are really distinct from the essence of the soul and from one another (Wippel, 1981, 176-84, 202-7).

If the soul's immanent operations such as thinking or willing inhere in their respective powers, the intellect and the will, those powers themselves cannot be the efficient causes of such acts. Against Henry of Ghent and later in Quodlibet XV against the Franciscan Gonsalvus of Spain, Godfrey denies that any exception can be made to the act-potency axiom. The will cannot reduce itself from potency to act or immediately efficiently cause its acts of volition. The efficient cause of volition can only be the object presented to the will by the intellect. Against the charge of intellectual determinism sometimes attributed to this position by its critics, Godfrey grounds human freedom in the radical indeterminacy, he even speaks of the freedom, of the intellect itself. And in his final Quodlibet XV, q. 4, he argues that if, *per impossibile*, the will could move itself directly without being moved by its object, freedom would be less well preserved than if one maintains with him that the will is moved by its object and then moves the apprehensive powers to their respective acts and, by means of such motions, indirectly moves itself with respect to secondary objects of volition (PB 14.20-23; Putallaz, 1995, 184-87, 198-208, 233-47).

11. Theory of Abstraction

According to Godfrey the agent intellect and the possible intellects are distinct powers of the individual human soul. His theory of intellectual knowledge is based on the agent intellect's ability to abstract potentially intelligible content from phantasms (images) produced by the imagination, an internal sense. The imagination depends upon the external senses for the data preserved in the phantasms. In Quodlibet V, q. 10 he makes a studied effort to explain in what the process of abstraction from phantasms consists

as he responds to the question whether the agent intellect produces any positive disposition in the phantasm. One of the functions of the agent intellect is to illuminate phantasms so that they can move the possible intellect to understand. Because the possible intellect is at times only in potency with respect to an intelligible object, and because nothing can reduce itself from potency to act, it must be reduced to the act of understanding by something else. Hence the agent intellect must in some way enable phantasms to move or to actualize the possible intellect.

But, argues Godfrey, because phantasms exist in the imagination and are organic and individuated and therefore incapable of moving a purely spiritual power which knows in universal fashion, the agent intellect does not introduce any positive disposition into the phantasms. Such a disposition would itself be individuated and organic and incapable of moving the possible intellect. He concludes, therefore, that the agent intellect operates on the phantasm simply by removing or separating or isolating one factor present therein--the quiddity of the thing, from another--its individuating characteristics. What has been so removed or separated or abstracted is thereby rendered universal and capable of moving the possible intellect. In what would become a frequently cited illustration, he draws an analogy with milk which possesses both color (white) and taste (sweet). Without the influence of light, however, it could not manifest itself or be perceived under the species of color (as white) without also manifesting itself under the species of taste (as sweet). Because of the influence of light one can speak of a kind of "abstraction" of the white from the sweet, although not in the sense that one would then exist apart from the other.

So, too, in the order of consideration although not in the order of reality, the agent intellect separates or frees the quiddity presented in a phantasm from its individuating conditions and thereby reduces it from being potentially intelligible to being actually intelligible and capable of moving the possible intellect to understand. This freeing or abstracting process takes place because of a kind of spiritual contact with the light of the agent intellect (Wippel, 1986).

12. Prime Matter

Godfrey defends the matter-form composition of corporeal beings but rejects any kind of spiritual matter and therefore any matter-form composition of spiritual entities. He also opposes the strong tendency within the Franciscan tradition, also promoted by Henry of Ghent, that would assign some minimum degree of actuality to prime matter. According to Godfrey prime matter is pure potentiality and can never be kept in existence without some substantial form, not even by God. Prime matter and substantial form are directly related to one another as potency principle and act principle. Neither is a being in its own right, but both are principles of one and the same composite entity (Quodlibet XIV, q. 5, PB 5.404-05).

13. Unicity vs. Plurality of Substantial Form

Heatedly debated in the 1270s and 1280s both at Paris and Oxford was the question concerning whether there is one or more than one substantial form in one substance, and especially in a human being. Godfrey devotes considerable attention to this, especially in Quodlibet II of Easter, 1286 and then again

in Quodlibet III of Christmas, 1286. These dates are significant because alleged theological difficulties with the theory of unicity of substantial form as advanced by Aquinas and others had led to prohibitions and condemnations of this by the Archbishop of Canterbury, Robert Kilwardby, O.P on March 18, 1277, a reissuing of this by his successor in that see, John Pecham, O.F.M. in 1284, and finally a new and resounding condemnation by Pecham on April 30, 1286.

In Quodlibet II, q. 7 Godfrey considers three theories that defend plurality of forms in all material substances, or at least of duality of substantial forms in human beings (Henry of Ghent). Godfrey severely criticizes all three theories. Most fundamental among his many arguments against them is his conviction that a substantial form confers substantial being upon a composite substance. Therefore, the presence of more than one substantial form in such a being would undermine its substantial unity. Already in this discussion Godfrey addresses alleged theological issues raised against unicity of substantial form, especially one concerning the continuing numerical identity of Christ's body during the period between his death on Good Friday and his resurrection on Easter Sunday. At this point Godfrey's philosophical preference is for unicity of form in all material entities, including humans. He regards theories that defend plurality of forms in all material substances as more improbable, and Henry's theory of duality of forms in human beings as less improbable. He maintains that the theological question remains open to a defense either of unicity or of plurality of substantial forms.

In Quodlibet III, q. 5, after Pecham's condemnation of April, 1286, Godfrey examines the theological aspects of this issue in detail. Again he insists on one's freedom, theologically speaking, to defend either unicity or plurality of forms in human beings, especially at Paris, but does not commit himself definitively to either side (PB 2.197-211). In sum, when he is primarily concerned with the philosophical issues involved, he favors unicity of substantial form in all material substances. When discussing the theological issues, he is more hesitant and, without embracing either side in any definitive way, continues to argue for one's freedom to defend either side pending some future decision by the Church (Wippel, 1981, pp, 321-47).

14. The Principle of Individuation

Together with many of his contemporaries, Godfrey attempts to identify the principle within material entities that accounts for their being multiplied numerically within species. In discussing this he returns to the distinction he had drawn in Quodlibet VI, q. 16 between the kind of unity which serves as a principle of number and which is based on discrete quantity, and the kind that is convertible with being, transcendental unity. Because the substantial form is the determining principle within a corporeal entity and makes its essence capable of being defined, Godfrey holds that it is by reason of its form that such a substance enjoys transcendental unity.

Nonetheless, in Quodlibet VII, q. 5 he comments that if different individuals within the same species share in the same specific nature, that nature cannot itself serve as the principle that renders them numerically distinct from one another. Something else seems to be needed, perhaps quantity. But to make quantity the principle of individuation will not resolve the problem, for this would be to reduce the

principle that distinguishes one substance from others within the same species to the level of an accident. Godfrey notes that in the case of created immaterial beings (angels), their substantial form is also that by which they are individuals. He proposes, therefore, that in corporeal substances it is also the substantial form that serves as their principle of individuation. Nonetheless, quantity has its role to play as well since it is required in order to divide matter into distinct parts and thereby enable it to receive and individuate substantial forms of the same kind. In other words, quantity disposes matter so as to enable it to function as the material principle of individuation. The formal cause or principle of a thing's individuation is its substantial form. Quantity is not the formal principle of individuation, but by disposing matter so that it can receive different substantial forms, it may be described as a quasi-material disposing cause of individuation (Wippel, 1981, 349-64).

Causation and Manipulability

Manipulablity theories of causation, according to which causes are to be regarded as handles or devices for manipulating effects, have considerable intuitive appeal and are popular among social scientists and statisticians. This article surveys several prominent versions of such theories advocated by philosophers, and the many difficulties they face. Philosophical statements of the manipulationist approach are generally reductionist in aspiration and assign a central role to human action. These contrast with recent discussions employing a broadly manipulationist framework for understanding causation, such as those due to the computer scientist Judea Pearl and others, which are non-reductionist and rely instead on the notion of an intervention. This is simply an appropriately exogenous causal process; it has no essential connection with human action. This interventionist framework manages to avoid at least some of these difficulties faced by traditional philosophical versions of the manipulability theory and helps to clarify the content of causal claims.

1. Introduction

A commonsensical idea about causation is that causal relationships are relationships that are potentially exploitable for purposes of manipulation and control: very roughly, if *C* is genuinely a cause of *E*, then if I can manipulate *C* in the right way, this should be a way of manipulating or changing *E*. This idea is the cornerstone of manipulability theories of causation developed by philosophers such as Gasking (1955), Collingwood (1940), von Wright (1971), and Menzies and Price (1993). It is also an idea that is advocated by many non-philosophers. For example, in their extremely influential text on experimental design (1979) Cook and Campbell write:

> *The paradigmatic assertion in causal relationships is that manipulation of a cause will result in the manipulation of an effect.* … Causation implies that by varying one factor I can make another vary. [Cook & Campbell, 1979, p. 36, emphasis in original.]

Similar ideas are commonplace in econometrics and in the so-called structural equations or causal modeling literature, and very recently have been forcefully reiterated by the computer scientist Judea Pearl in an impressive book length treatment of causality (Pearl, 2000).

To a large extent, however, recent philosophical discussion has been unsympathetic to manipulability theories: it is claimed both that they are unilluminatingly circular and that they lead to a conception of causation that is unacceptably anthropocentric or at least insufficiently general in the sense that it is linked much too closely to the practical possibility of human manipulation. (See, e.g., Hausman, 1986, 1998). Both objections seem prima-facie plausible. Suppose that *X* is a variable that takes one of two different values, 0 and 1, depending on whether some event of interest occurs. Then for an event or process *M* to qualify as a manipulation of *X*, it would appear that there must be a causal connection between *M* and *X*: to manipulate *X*, one must *cause* it to change in value. How then can we use the notion of manipulation to provide an account of causation? Moreover, it is uncontroversial that causal relationships can obtain in circumstances in which manipulation of the cause by human beings is not practically possible -- think of the causal relationship between the gravitational attraction of the moon and the motion of the tides or causal relationships in the very early universe. How can a manipulability theory avoid generating a notion of causation that is so closely tied to what humans can do that it is inapplicable to such cases?

As remarked above, the generally negative assessment of manipulability theories among philosophers contrasts sharply with the widespread view among statisticians, theorists of experimental design, and many social and natural scientists that an appreciation of the connection between causation and manipulation can play an important role in clarifying the meaning of causal claims and understanding their distinctive features. This in turn generates a puzzle. Are non-philosophers simply mistaken in thinking that focusing on the connection between causation and manipulation can tell us something valuable about causation? Does the widespread invocation of something like a manipulability conception among practicing scientist show that the usual philosophical criticisms of manipulability theories of causation are misguided?

The ensuing discussion is organized as follows. §§2 and 3 describe two of the best known philosophical

formulations of the manipulability theory -- those due to von Wright (1971) and Menzies and Price (1993) -- and explore certain difficulties with them. §4 argues that the notion of a free action cannot play the central role it is assigned in traditional versions of manipulability theories. §5 introduces the notion of an intervention which allows for a more adequate statement of the manipulability approach to causation and which has figured prominently in recent discussion. §6 considers Pearl's "interventionist" formulation of a manipulability theory and an alternative to it, due to Woodward. §§7 and 8 take up the charge that manipulability theories are circular. §9 returns to the relationship between interventions and human actions, while §10 compares manipulability accounts with David Lewis' closely related counterfactual theory of causation. Finally, §11 considers whether there are meaningful causal claims that cannot be captured by a manipulability theory.

As we shall see, the different assessments of manipulability accounts of causation within and outside of philosophy derive from the different goals or aspirations that underlie the versions of the theory developed by these two groups. Philosophical defenders of the manipulability conception have typically attempted to turn the connection between causation and manipulability into a reductive analysis: their strategy has been to take as primitive the notion of manipulation (or some related notion like agency or bringing about an outcome as a result of a free action), to argue that this notion is not itself causal (or at least does not presuppose all of the features of causality the investigator is trying to analyze), and to then attempt to use this notion to construct a non-circular reductive definition of what it is for a relationship to be causal. Philosophical critics have (quite reasonably) assessed such approaches in terms of this aspiration (i.e., they have tended to think that manipulability accounts are of interest only insofar as they lead to a non-circular analysis of causal claims) and have found the claim of a successful reduction unconvincing. By contrast, statisticians and other non-philosophers who have explored the link between causation and manipulation generally have not had reductionist aspirations-instead their interest has been in unpacking what causal claims mean and in showing how they figure in inference by tracing their interconnections with other related concepts (such as manipulation) but without suggesting that the notion of manipulation is itself a causally innocent notion.

It is the impulse toward reduction that generates the other feature that critics have found objectionable in standard formulations of the manipulability theory. To carry through the reduction, one needs to show that the notion of agency is independent of or prior to the notion of causality and this in turn requires that human actions or manipulations be given a special status-they can't be ordinary causal transactions, but must instead be an independent fundamental feature of the world in their own right. This both seems problematic on its own terms (it is prima-facie inconsistent with various naturalizing programs) and leads directly to the problem of anthropocentricity: if the only way in which we understand causation is by means of our prior grasp of an independent notion of agency, then it is hard to see what could justify us in extending the notion of causation to circumstances in which manipulation by human beings is not possible and the relevant experience of agency unavailable. As we shall see, both von Wright and Menzies and Price struggle, not entirely successfully, with this difficulty.

The way out of these problems is to follow writers like Pearl in reformulating the manipulability approach in terms of the notion of an intervention, where this is characterized in purely causal terms that make no essential reference to human action. Some human actions will qualify as interventions but they

will do so in virtue of their causal characteristics, not because they are free or carried out by humans. This "interventionist" reformulation allows the manipulability theory to avoid a number of counterexamples to more traditional versions of the theory. Moreover, when so reformulated, the theory may be extended readily to capture causal claims in contexts in which human manipulation is impossible. However, the price of such a reformulation is that we lose the possibility of a reduction of causal claims to claims that are non-causal. Fortunately (or so §§7 and 8 argue) an interventionist formulation of a manipulability theory may be non-trivial and illuminating even if it fails to be reductive.

2. von Wright

In his (1971) von Wright describes the basic idea of the manipulability approach as follows:

> … to think of a relation between events as causal is to think of it under the aspect of (possible) action. It is therefore true, but at the same time a little misleading to say that if *p* is a (sufficient) cause of *q*, then if I could produce *p* I could bring about *q*. For *that p* is the cause of *q*, I have endeavored to say here, *means* that I could bring about *q*, if I could do (so that) *p*. (p. 74)

To the objection that "doing" or "producing" is already a causal notion and hence not something to which we can legitimately appeal to elucidate the notion of causation, von Wright responds as follows:

> The connection between an action and its result is intrinsic, logical and not causal (extrinsic). If the result does not materialize, the action simply has not been performed. The result is an essential "part" of the action. It is a *bad* mistake to think of the act(ion) itself as a cause of its result. (pp. 67-8)

Here we see a very explicit attempt to rebut the charge that an account of causation based on agency is circular by contending that the relation between an action (or a human manipulation) and its result is not an ordinary causal relation. Moreover, von Wright readily embraces the further conclusion that seems to follow from this: human action must be a concept which, in our understanding of the world, is just as "basic" as the notion of causality (p. 74).

Given the logical structure of von Wright's views, it is also not surprising, to find him struggling to make sense of the idea that there can be causal relations involving events that human beings cannot in fact manipulate. He writes:

> The eruption of Vesuvius was the cause of the destruction of Pompeii. Man can through his action destroy cities, but he cannot, we think, make volcanoes erupt. Does this not prove that the cause-factor is not distinguished from the effect-factor by being in a certain sense capable of manipulation? The answer is negative. The eruption of a volcano and the destruction of a city are two very complex events. Within each of them a number of events

> or phases and causal connections between them may be distinguished. For example, that when a stone from high above hits a man on his head, it kills him. Or that the roof of a house will collapse under a given load. Or that a man cannot stand heat above a certain temperature. All these are causal connections with which we are familiar from experience and which are such that the cause-factor typically satisfies the requirement of manipulability. (p. 70)

von Wright's view is that to understand a causal claim involving a cause that human beings cannot in fact manipulate (e.g., the eruption of a volcano) we must interpret it in terms of claims about causes that human beings *can* manipulate (impacts of falling stones on human heads and so on). We will return to this general idea below in connection with Price and Menzies but it is worth noting that it faces an obvious problem. If we try to explain what it means to say that different galaxies attract one another gravitationally by contending that such interactions are in some relevant respects similar to gravitational interactions with which we are familiar or have experience (people and projectiles falling to earth), we need to explain what "similar" means and it is very hard to see how to do this within the framework of an agency theory. The relevant notion of similarity does not seem to be a notion that can be spelled out in terms of similarities in people's experiences of agency. Either we explain the relevant notion of similarity in straightforwardly causal terms that seem to have nothing to do with agency (e.g., we say that the similarity consists in the fact that the same gravitational force law is operative in both cases), in which case we have effectively abandoned the agency theory, or else we are led to the conclusion that causal claims involving unmanipulable causes like galaxies involve a conception of causality which is fundamentally different from the conception that is applicable to manipulable causes.

3. Menzies and Price

A very similar dialectic is at work in an extremely interesting recent paper by Peter Menzies and Huw Price (1993) (and in a series of papers written by Price alone, 1991, 1992) which represents the most detailed and sustained attempt in the recent philosophical literature to develop an "agency" theory of causation. Price and Menzies basic thesis is that:

> … an event *A* is a cause of a distinct event *B* just in case bringing about the occurrence of *A* would be an effective means by which a free agent could bring about the occurrence of *B*. (1993, p. 187)

They take this connection between free agency and causation to support a probabilistic analysis of causation (according to which "*A* causes *B*" can be plausibly identified with "*A* raises the probability of *B*") provided that the probabilities appealed to are what they call "agent probabilities," where

> [a]gent probabilities are to be thought of as conditional probabilities, assessed from the agent's perspective under the supposition that antecedent condition is realized ab initio , as a free act of the agent concerned. Thus the agent probability that one should ascribe to *B* conditional on *A* is the probability that *B* would hold were one to choose to realize *A*.

> (1993, p. 190)

The idea is thus that the agent probability of *B* conditional on *A* is the probability that *B* would have conditional on the assumption that *A* has a special sort of status or history -- in particular, on the assumption that A is realized by a free act. *A* will be a cause of *B* just in case the probability of *B* conditional on the assumption that *A* is realized by a free act is greater than the unconditional probability of *B*; *A* will be a spurious cause of *B* just in case these two probabilities are equal. As an illustration, consider a stock example of philosophers -- a structure in which atmospheric pressure, represented by a variable *Z*, is a common cause of the reading *X* of a barometer and the occurrence of a storm *Y*, with no causal relationship between *X* and *Y*. *X* and *Y* will be correlated, but Price's and Menzies' intuitive idea is that conditional on the realization of *X* by a free act, this correlation will disappear, indicating that the correlation between *X* and *Y* is spurious and does not reflect a causal connection from *X* to *Y*. If, by contrast, this correlation were to persist, this would be an indication that *X* was after all a cause of *Y*. (What "free act" might mean in this context will be explored below, but I take it that what is *intended* -- as opposed to what Price and Menzies actually say -- is that the manipulation of *X* should satisfy the conditions we would associate with an ideal experiment designed to determine whether *X* causes *Y* -- thus, for example, the experimenter should manipulate the position of the barometer dial in a way that is independent of the atmospheric pressure *Z*, perhaps by setting its value after consulting the output of some randomizing device.)

Like von Wright, Price and Menzies attempt to appeal to this notion of agency to provide a non-circular, reductive analysis of causation. They claim that circularity is avoided because we have a grasp of the *experience* of agency that is independent of our grasp of the general notion of causation.

> The basic premise is that from an early age, we all have direct experience of acting as agents. That is, we have direct experience not merely of the Humean succession of events in the external world, but of a very special class of such successions: those in which the earlier event is an action of our own, performed in circumstances in which we both desire the later event, and believe that it is more probable given the act in question than it would be otherwise. To put it more simply, we all have direct personal experience of doing one thing and thence achieving another. … It is this common and commonplace experience that licenses what amounts to an ostensive definition of the notion of 'bringing about'. In other words, these cases provide direct non-linguistic acquaintance with the concept of bringing about an event; acquaintance which does not depend on prior acquisition of any causal notion. An agency theory thus escapes the threat of circularity. (1993, p. 194-5)

Again like von Wright, Menzies and Price recognize that, once the notion of causation has been tied in this way to our "personal experience of doing one thing and hence achieving another" (1993, p. 194), a problem arises concerning unmanipulable causes. To use their own example, what can it mean to say that "the 1989 San Francisco earthquake was caused by friction between continental plates" (p. 195) if no one has (or given the present state of human capabilities could have) the direct personal experience of bringing about an earthquake by manipulating these plates? Their response to this difficulty is complex, but the central idea is captured in the following passages

> … we would argue that when an agent can bring about one event as a means to bringing about another, this is true in virtue of certain basic intrinsic features of the situation involved, these features being essentially non-causal though not necessarily physical in character. Accordingly, when we are presented with another situation involving a pair of events which resembles the given situation with respect to its intrinsic features, we infer that the pair of events are causally related even though they may not be manipulable. (1993, p. 197)

> Clearly, the agency account, so weakened, allows us to make causal claims about unmanipulable events such as the claim that the 1989 San Francisco earthquake was caused by friction between continental plates. We can make such causal claims because we believe that there is another situation that models the circumstances surrounding the earthquake in the essential respects and does support a means-end relation between an appropriate pair of events. The paradigm example of such a situation would be that created by seismologists in their artificial simulations of the movement of continental plates. (1993, p. 197)

The problem with this strategy parallels the difficulty with von Wright's broadly similar suggestion. What is the nature of the "intrinsic" but (allegedly) "non-causal" features in virtue of which the movements of the continental plates "resemble" the artificial models which the seismologists are able to manipulate? It is well-known that small scale models and simulations of naturally occurring phenomena that superficially resemble or mimic those phenomena may nonetheless fail to capture their causally relevant features because, for example, the models fail to "scale up" -- because causal processes that are not represented in the model become quite important at the length scales that characterize the naturally occurring phenomena. Thus, when we ask what it is for a model or simulation which contains manipulable causes to "resemble" phenomena involving unmanipulable causes, the relevant notion of resemblance seems to require that the same *causal* processes are operative in both. Price and Menzies provide no reason to believe that this notion of resemblance can be characterized in non-causal terms. But if the extension of their account to unmanipulable causes requires a notion of resemblance that is already causal in character and which, ex hypothesi cannot be explained in terms of our experience of agency, then their reduction fails.

It might be thought the difficulty under discussion can be avoided by the simple expedient of adhering to a counterfactual formulation of the manipulability theory. Indeed, it is clear that *some* counterfactual formulation is required if the theory is to be even remotely plausible: after all, no one supposes that *A* can only be a cause of *B* if *A* is in fact manipulated. Instead, the intuitive core of the manipulability theory should be formulated as the claim (**CF**):

> (**CF**) *A* causes *B* if and only if *B* would change if an appropriate manipulation on *A* *were* to be carried out.

The suggestion under consideration attempts to avoid the difficulties posed by causes that are not manipulable by human beings by contending that for (**CF**) to be true, it is not required that the manipulation in question be practically possible for human beings to carry out or even that human beings exist. Instead all that is required is that *if* human beings were to exist and to carry out the requisite manipulation of *A* (e.g. the continental plates), *B* (whether or not an earthquake occurs) would change. (The possibility of adopting such a counterfactual formulation is sympathetically explored, but not fully endorsed by Ernest Sosa and Michael Tooley in the introduction to their (1993))

One fundamental problem with this suggestion is that, independently of whether a counterfactual formulation is adopted, the notion of a free action or human manipulation cannot by itself, for reasons to be described in Section 4, do the work (that of distinguishing between genuine and spurious causal relationships) that Menzies and Price wish it to do. But in addition to this, a counterfactual formulation along the lines of (**CF**) seems completely unilluminating unless accompanied by some sort of account of how we are to understand and assess such counterfactuals and, more specifically, what sort of situation or possibility we are supposed to envision when we imagine that the antecedent of (**CF**) is true. Consider, for example, a causal claim about the very early universe during which temperatures are so high that atoms and molecules and presumably anything we can recognize as an agent cannot exist. What counterfactual scenario or possible world are we supposed to envision when we ask, along the lines of (**CF**), what would happen if human beings were to exist and were able to carry out certain manipulations in this situation? A satisfying version of an agency theory should give us an account of how our experience of agency in ordinary contexts gives us a purchase on how to understand and evaluate such counterfactuals. To their credit, von Wright and Price and Menzies attempt to do this, but in my view they are unsuccessful.

4. Causation and Free Action

As we have seen, Menzies and Price assign a central role to "free action" in the elucidation of causation. They do not further explain what they mean by this phrase preferring instead, as the passage quoted above indicates, to point to a characteristic experience we have as agents. It seems clear, however, that whether (as soft determinists would have it) a free action is understood as an action that is uncoerced or unconstrained or due to voluntary choices of the agent, or whether, as libertarians would have it, a free action is an action that is uncaused or not deterministically caused, the persistence of a correlation between *A* and *B* when *A* is realized as a "free act" is *not* sufficient for *A* to cause *B*. Suppose that, in the example described above, the position of the barometer dial *X* is set by a free act (in either of the above senses) of the experimenter but that that this free act (and hence *X*) is correlated with *Z*, the variable measuring atmospheric pressure, perhaps because the experimenter observes the atmospheric pressure and freely chooses to set *X* in a way that is correlated with *Z*. (This possibility is compatible with the experimenter's act of setting *X* being free in either of the above two senses.) In this case, *X* will remain correlated with *Y* when produced by a free act, even though *X* does not cause *Y*. Suppose, then, that we respond to this difficulty by adding to our characterization of *A's* being realized by a free act the idea that this act must not itself be correlated with any other cause of *A*. (Passages in Price, 1991 suggest such an additional proviso, although the condition in question seems to have nothing to do with the usual

understanding of free action.) Even with this proviso, it need not be the case that *A* causes *B* if *A* remains correlated with *B* when *A* is produced by an act that is free in this sense, since it still remains possible that the free act that produces *A* also causes *B* via a route that does not go through *A*. As an illustration, consider a case in which an experimenter's administration of a drug to a treatment group (by inducing patients to ingest it) has a placebo effect that enhances recovery, even though the drug itself has no effect on recovery. There is a correlation between ingestion of the drug and recovery that persists under the experimenter's free act of administering the drug even though ingestion of the drug does not cause recovery.

5. Interventions

Examples like those just described show that if we wish to follow Menzies and Price in defending the claim that if an association between *A* and *B* persists when *A* is given the right sort of "independent causal history" or is "manipulated" in the right way, then *A* causes *B*, we need to be much more precise by what we mean by the quoted phases. There have been a number of attempts to do this in the recent literature on causation. The basic idea that all of these discussions attempt to capture is that of a "surgical" change in *A* which is of such a character that if any change occurs in *B*, it occurs only as a result of its causal connection, if any, to *A* and not in any other way. In other words, the change in *B*, if any, that is produced by the manipulation of *A* should be produced only via a causal route that goes through *A*. Manipulations or changes in the value of a variable that have the right sort of surgical features have come to be called *interventions* in the recent literature (e.g. Spirtes, Glymour and Scheines, 1993, Meek and Glymour, 1994, Hausman, 1998, Pearl, 2000, Woodward, 1997, 2000, Woodward and Hitchcock, forthcoming, Cartwright, forthcoming) and I will follow this practice. The characterization of the notion of an intervention is rightly seen by many writers as central to the development of a plausible version of a manipulability theory . One of the most detailed attempts to think systematically about interventions and their significance for understanding causation is due to Pearl, 2000 and I turn now to a discussion of his views.

6. Pearl

Pearl uses systems of equations and directed graphs to represent causal relationships and his work provides a striking illustration of the heuristic usefulness of a manipulationist framework in specifying what it is to give such systems a causal interpretation.[1] Pearl characterizes the notion of an intervention by reference to a primitive notion of a causal mechanism. A functional causal model is a system of equations $X_i = F(Pa_i, U_i)$ where Pa_i represents the parents or direct causes of X_i that are explicitly included in the model and U_i represents an error variable that summarizes the impact of all excluded variables. Each equation represents a distinct causal mechanism which is understood to be "autonomous" in the sense in which that notion is used in econometrics; this means roughly that it is possible to interfere with or disrupt each mechanism (and the corresponding equation) without disrupting any of the others. The simplest sort of intervention in which some variable X_i is set to some particular value x_i

amounts, in Pearl's words, to "lifting X_i from the influence of the old functional mechanism $X_i = F_i$ (Pa_i, U_i) and placing it under the influence of a new mechanism that sets the value x_i while keeping all other mechanisms undisturbed." (Pearl, 2000, p. 70; I have altered the notation slightly). In other words, the intervention disrupts completely the relationship between X_i and its parents so that the value of X_i is determined entirely by the intervention. Furthermore, the intervention is surgical in the sense that no other causal relationships in the system are changed. Formally, this amounts to replacing the equation governing X_i with a new equation $X_i = x_i$, substituting for this new value of X_i in all the equations in which X_i occurs but leaving the other equations themselves unaltered. Pearl's assumption is that the other variables that change in value under this intervention will do so only if they are effects of X_i.

Following Pearl, let us represent the proposition that the value of *X* has been set by an intervention to some particular value, x_0, by means of a "*do*" operator ($do(X=x_0)$, or more simply, $do\ x_0$). It is important to understand that conditioning on the information that the value of *X* has been set to x_0 will in general be quite different from conditioning on the information that the value of *X* has been observed to be x_0. (See Meek and Glymour, 1994; Pearl, 2000.) For example, in the case in which *X* and *Y* are joint effects of the common cause *Z*, $P(Y/X=x_0) \neq P(Y)$; that is, *Y* and *X* are not independent. However, $P(Y/do(X=x_0) = P(Y)$; that is, *Y* will be independent of *X*, if the value of *X* is set by an intervention. This is because the intervention on *X* will break the causal connection from *Z* to *X*, so that the probabilistic dependence between *Y* and *X* that is produced by *Z* in the undisturbed system will no longer hold once the intervention occurs. In this way, we may capture Menzies' and Price's idea that *X* causes *Y* if and only if the correlation between *X* and *Y* would persist under the right sort of manipulation of *X*.

This framework allows for a simple definitions of various causal notions. For example, Pearl defines the "causal effect" of *X* on *Y* associated with the "realization" of a particular value *x* of *X* as:

(**C**) $P(y/do\ x)$,

that is, as the distribution that *Y* would assume under an intervention that sets the value of *X* to the value *x*. It is obvious that this is a version of a counterfactual account of causation.

One of the many attractions of this approach is that it yields a very natural account of what it is to give a causal interpretation to a system of equations of the sort employed in the so-called causal modeling literature. For example, if a linear regression equation $Y = aX + U$ makes a causal claim, it is to be understood as claiming that if an intervention were to occur that sets the value of $X=x_0$ in circumstances $U=u_0$, the value of *Y* would be $y = ax_0 + u_0$, or alternatively that an intervention that changes *X* by amount *dx* will change *Y* by amount *a dx*. As another illustration consider the system of equations

(1) $Y = aX + U$
(2) $Z = bX + cY + V$

We may rewrite these as follows

(1) $Y = aX + U$
(3) $Z = dX + W$

where $d = b + ac$ and $W = cU + V$. Since (3) has been obtained by substituting (1) into (2), the system (1)-(2) has exactly the same solutions in *X* , *Y* , and *Z* as the system (1)-(3). Since *X*, *Y* and *Z* are the only measured variables, (1)-(2) and (1)-(3) are "observationally equivalent" in the sense that they imply or represent exactly the same facts about the patterns of correlations that obtain among the measured variables. Nonetheless two systems correspond to different causal structures. (1)-(2) says that *X* is a direct cause of *Y* and that *X* and *Y* are direct causes of *Z*. By contrast, (1)-(3) says that *X* is a direct cause of *Y* and that *X* is a direct cause of *Z* but says nothing about a causal relation between *Y* and *Z*. We can cash this difference out within the interventionist/manipulationist framework described above -- (2) claims that an intervention on *Y* will change *Z* while (3) denies this. (Recall that an intervention on *Y* with respect to *Z* must not be correlated with any other cause of *Z* such as *X*, and will break any causal connection between *X* and *Y*.) Thus while the two systems of equations agree about the correlations so far observed, they disagree about what would happen under an intervention on *Y*. According to an interventionist/manipulationist account of causation, it is the system that gets such counterfactuals right that correctly represents the causal facts.

One possible limitation of Pearl's characterization of an intervention concerns the scope of the requirement that an intervention on X_i leave intact *all* other mechanisms besides the mechanism that previously determined the value of X_i. If, as Pearl apparently intends, we understand this to include the requirement that an intervention on X_i must leave intact the causal mechanism if any, that connects X_i to its possible effects *Y*, then an obvious worry about circularity arises, at least if we want to use the notion of an intervention to characterize what it is for X_i to cause *Y*. A closely related problem is that given the way Pearl characterizes the notion of an intervention, his definition (**C**) of the causal effect of *X* on *Y*, seems to give us not the causal contribution made by $X = x$ alone to *Y* but rather the combined impact on *Y* of this contribution and whatever contribution is made to the value of *Y* by other causes of *Y* besides *X*. For example, in the case of the the regression equation $Y = aX+U$, the causal effect in Pearl's sense of *X=x on Y* is apparently $P(Y) = ax + U$, rather than, as one might expect, just *ax*. In part for these reasons,Woodward (1997, 2000) and Woodward and Hitchcock (forthcoming)explore a different way of characterizing the notion of an intervention which does not make reference to the relationship between the variable intervened on and its effects. For Woodward and Hitchcock, in contrast to Pearl, an intervention *I* on a variable *X* is always defined with respect to a second variable *Y* (the intent being to use the notion of an intervention on *X* with respect to *Y* to characterize what it is for *X* to cause *Y*). Such an intervention *I* must meet the following requirements (**M1**) - (**M4**):

(**M1**) *I* must be the only cause of *X*; i.e., as with Pearl, the intervention must completely disrupt the causal relationship between *X* and its previous causes so that the value of *X* is set entirely by *I*,

(**M2**) *I* must not directly cause *Y* via a route that does not go through *X* as in the placebo example,

(**M3**) *I* should not itself be caused by any cause that affects *Y* via a route that does not go through *X*, and

(**M4**) *I* leaves the values taken by any causes of *Y* except those that are on the directed path from *I* to *X* to *Y* (should this exist) unchanged.

Within this framework, the most natural way of defining the notion of causal effect is in terms of the *difference* made to the value of *Y* by a change or difference in the value of *X*. Focusing on differences in this way allows us to isolate the contribution made to *Y* by *X* alone from the contribution made to *Y* by its other causes. Moreover, since in the non-linear case, the change in the value of *Y* caused by a given change in the value of *X* will depend on the values of the other causes of *Y*, it seems to follow that the notion of causal effect must be relativized to a background context B_i which incorporates information about these other values. In deterministic contexts, we might thus define the causal effect on *Y* of a change in the value of *X* from $X=x$ to $X=x'$ in circumstances B_i as:

(**CD**) $Y_{do\ x,\ B_i} - Y_{do\ x',\ B_i}$,

that is, as the difference between the value that *Y* would take under an intervention that sets $X=x$ in circumstances B_i and the value that *Y* would take under an intervention that sets $X=x'$ in B_i, where the notion of an intervention is now understood in terms of (**M1**) - (**M4**) rather than in the way recommended by Pearl. In non-deterministic contexts, the definition of causal effect is, analogously, $P_{do\ x,B_i}(Y) - P_{do\ x',B_i}(Y)$. In the deterministic case, *X* will then be a cause of *Y* in B_i if and only if the causal effect of *X* on *Y* in B_i is non-zero for some pair of values of *X* - that is, if and only if there are distinct values of *X*, *x* and x' such that the value of *Y* under an intervention that sets $X=x$ in B_i is different from the value of *Y* under an intervention that sets $X=x'$. In probablistic contexts, *X* will be a cause of *Y* if the probability distribution of *Y* is different for two different values of *X*, when these are set by interventions.

I will not attempt to adjudicate here among these and various other proposals concerning the best way to characterize the notions of intervention and causal effect. Instead, I want to comment on the general strategy they embody and to compare it with the approach to causation associated with theorists like Menzies and Price. Note first that the notion of an intervention, when understood along either of the lines described above, is an unambiguously causal notion in the sense that causal notions are required for its characterization -- thus the proposals variously speak of an intervention on *X* as breaking the causal connection between *X* and its causes while leaving other causal mechanisms intact or as not affecting *Y* via a causal route that does not go through *X*. This has the immediate consequence that one cannot use the notion of an intervention to provide a reduction of causal claims to non-causal claims. Moreover, to the extent that reliance on some notion like that of an intervention is unavoidable in any satisfactory version of a manipulability theory (as I believe that it is), any such theory must be non-reductionist. Indeed, we can now see that critics who have charged manipulability theories with circularity have in one

important sense understated their case: manipulability theories turn out to be "circular" not just in the obvious sense that for an action or event *I* to constitute a an intervention on a variable *X*, there must be a causal relationship between *I* and *X*, but in the sense that *I* must meet a number of other causal conditions as well.

7. Is Circularity a Problem?

Suppose that we agree that any plausible version of a manipulability theory must make use of the notion of an intervention and that this must be characterized in causal terms. Does this sort of "circularity" make any such theory trivial and unilluminating? It seems to me that it does not, for at least two reasons. First, it may be, as writers like Woodward contend, that in characterizing what it is for a process *I* to qualify as an intervention on *X* for the purposes of characterizing what it is for *X* to cause *Y*, we need not make use of information about the causal relationship, if any, between *X* and *Y*. Instead, it may be that we need only to make use of *other* sorts of causal information, e.g., about the causal relationship between *I* and *Y* or about whether *I* is caused by causes that cause *Y* without causing *X*, as in (**M1**) - (**M4**) above. To the extent that this is so, we may use one set of claims about causal relationships (e.g., that *X* has been changed by a process that meets the conditions for an intervention) together with correlational information (that *X* and *Y* remain correlated under this change) to characterize what it is for a different relationship (the relationship between *X* and *Y*) to be causal. This does not yield a reduction of causal talk to non-causal talk, but it is also not viciously circular in the sense that it presupposes that we already have causal information about the very relationship that we are trying to characterize. One reason for thinking that there must be *some* way of characterizing the notion of an intervention along the lines just described is that we do sometimes learn about causal relationships by performing experiments -- and it is not easy to see how this is possible if to characterize the notion of an intervention on *X* we had to make reference to the causal relationship between *X* and its effects.

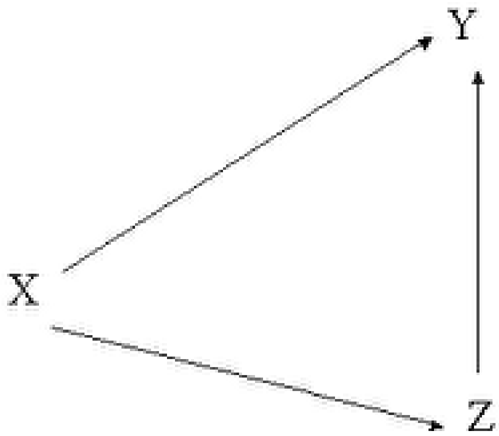
8. The Plurality of Causal Concepts

A second respect in which reliance on the notion of an intervention need not be thought of as introducing a vicious circularity is this: So far, I have been following von Wright and Menzies and Price in assuming that there is just one causal notion or locution (*A* causes *B*, where *A* and *B* are types of events) that we are trying to analyze. But in fact there are many such notions. For example, among causal notions belonging to the family of so-called type causal notions (i.e., causal claims that relate types of events or variables) there is a distinction to be drawn between what we might call claims about total or net causes and claims about direct causes. Even if the notion of an intervention presupposes some causal notion such as some notion of type causation, it may be that we can use it to characterize other causal notions.

As an illustration consider the causal structure represented by the following equations and associated directed graph

$$Y = aX + cZ$$

$Z = bX$



In this structure, there are two different causal routes from *X* to *Y* -- a direct causal relationship and an indirect relationship with *Z* as an intermediate variable. If $a = -bc$, there is cancellation along these two routes. This means that no intervention on *X* will change the value of *Y*. In one natural sense, this seems to mean that *X* does not cause *Y*, just as (**C**) (§6) suggests. In another natural sense, however, *X* does seem to be a cause -- indeed a direct cause- of *Y*. We can resolve this apparent inconsistency by distinguishing between two kinds of causal claims[2] -- the claim *X* is a total or net cause of *Y*, where this is captured by (**C**)or (**CD**), and the claim that *X* is a direct cause of *Y*, where this is understood along the following lines: *X* is a direct cause of *Y* if and only if under some intervention that changes the value of *X*, the value of *Y* changes when all other variables in the system of interest besides *X* and *Y* including those that are on some causal route from *X* to *Y*, are held fixed at some value, also by interventions. (For related, but different, characterizations of direct causation along these lines, see Pearl, 2000 and Woodward, forthcoming) Fixing the other values of other variables means that each of these values are determined by separate processes, each meeting the conditions for an intervention, that are appropriately independent of each other and of the intervention that changes the value of *X*. The effect of intervening to fix the values of these variables is thus that each variable intervened on is disconnected from its causes, including *X*. In the example under discussion, *X* qualifies as a direct cause of *Y* because if we were to fix the value of *Z* in a way that disconnects it from the value of *X*, and then intervene to change the value of *X*, the value of *Y* would change. This idea can then be generalized to provide a characterization of "contributing" causation or causation along a causal route, i.e., to capture the sense in which *X* is an indirect cause of *Y* along the route that goes through *Z*. (Woodward, forthcoming).

One can also use the notion of an intervention to characterize what it is for the fact or event of *X*'s taking on some particular value to be an actual or token cause of *Y*'s taking on a particular value (as opposed to *X*'s being a type cause of *Y*) and in this way help to clarify the relationship between type and token causation. (See Pearl 2000, Hitchcock, 2001, Woodward, forthcoming). Thus even if a "manipulationist" or "interventionist" framework does not yield a reduction of causal talk to non-causal talk, it provides a natural way of marking the distinctions among a number of different causal notions and exhibiting their interrelations. More generally, even if a manipulationist account of causation does not yield a reduction but instead simply connects "causation" (or better, various more specific causal concepts) with other concepts within the same circle, we still face many non-trivial choices about how the concepts on this

circle are to be elucidated and connected up with one another. For example, it is far from obvious how to characterize the notion of an intervention so as to avoid the various counterexamples to standard statements of the manipulability theory such as the theory of Menzies and Price. It is in part because the notion of manipulation/intervention has an interesting and complex fine structure-a structure that is left largely unexplored in traditional manipulability theories-that working out the connection between causation and manipulation turns out to be interesting and non-trivial rather than banal and obvious.

9. Interventions That Do Not Involve Human Action

We noted above that a free action need not meet the conditions for an intervention, on any of the conceptions of intervention described in §6. It is also true that a process or event can qualify as an intervention even if it does not involve human action or intention at any point. This should be apparent from the way in the notion of an intervention has been characterized, for this is entirely in terms of causal and correlational concepts and makes no reference to human beings or their activities. In other words, a purely "natural" process involving no animate beings at all can qualify as an intervention as long as it has the right sort of causal history -- indeed, this sort of possibility is often described by scientists as a natural experiment. Moreover, even when manipulations are carried out by human beings, it is the causal features of those manipulations and not the fact that they are carried out by human beings or are free or are attended by a special experience of agency that matters for recognizing and characterizing causal relationships. Thus, by giving up any attempt at reduction and characterizing the notion of an intervention in causal terms, an "interventionist approach of the sort described under §§5 and 6 avoids the second classical problem besetting manipulability theories -- that of anthropocentrism and commitment to a privileged status for human action. For example, under this approach *X* will qualify as a (total) cause of *Y* as long as it is true that for some value of *X* that if *X* were to be changed to that value by a process having the right sort of causal characteristics, the value of *Y* would change. Obviously, this claim can be true even if human beings lack the power to manipulate *X* or even in a world in which human beings do not or could not exist. There is nothing in the interventionist version of a manipulability theory that commits us to the view that all causal claims are in some way dependent for their truth on the existence of human beings or involve a "projection" on to the world of our experience of agency.

10. Interventions and Counterfactuals

We noted above that interventionist versions of manipulability theories are counterfactual theories. What is the relationship between such theories and more familiar versions of counterfactual theories such as the theory of David Lewis? Lewis' theory is an account of what it is for one individual token event to cause another while (**C**) is formulated in terms of variables or types of events , but abstracting away from this and certain other differences, there are a number of striking similarities between the two approaches. As readers of Lewis will be aware, any counterfactual theory must explain what we should envision as changed and what should be held fixed when we evaluate a counterfactual the antecedent of which is not true of the actual world -- within Lewis' framework, this is the issue of which worlds in which the antecedent of the counterfactual holds are "closest" or "most similar" to the actual world. Lewis' answer

to this question invokes a "similarity" ordering that ranks the importance of various respects of resemblance between worlds in assessing overall similarity. (Lewis, 1979). For example, avoiding diverse, widespread violations of law is said to be the most important consideration, preserving perfect match of particular fact over the largest possible spatio-temporal region is next in importance and more important than avoiding small localized violations of law, and so on. As is well-known the effect of this similarity ordering is, at least in most situations, to rule out so-called "back-tracking" counterfactuals (e.g., the sort of counterfactual that is involved in reasoning that if the effect of some cause had not occurred, then the cause would not have occurred). When the antecedent of a counterfactual is not true of the actual world, Lewis' similarity metric leads us (at least in deterministic contexts) to think of that antecedent as made true by a "small" miracle.

The notion of an intervention plays a very similar role within manipulability theories of causation to Lewis' similarity ordering. Like Lewis' ordering, the characterization of an intervention tells us what should be envisioned as changed and what should be held fixed when we evaluate a counterfactual like "If *X* were to be changed by an intervention to such and such a value, the value of *Y* would change". (For example, on Pearl's understanding of an intervention, in evaluating this counterfactual, we are to consider a situation in which the previously existing causal relationship between *X* and its causes is disrupted, but all other causal relationships in the system of interest are left unchanged.) A moment's thought will also show that, as in Lewis' account, both Pearl's and Woodward's characterizations of interventions rule out backtracking counterfactuals -- for example, in evaluating a counterfactual of the form "if an intervention were to occur that changes *E*, (where *E* is an effect of *C*), then *C* would change", Pearl holds that we should consider a situation in which the relationship between *E* and its causes (in this case, *C*) is disrupted, but all other causal relationships are left unchanged, so that *C* still occurs, and the above counterfactual is false, as it should be. Moreover, there is a clear similarity between Lewis' idea that the appropriate counterfactuals for analyzing causation are counterfactuals the antecedents of which are made true by miracles, and the idea of an intervention as an exogenous change that disrupts the mechanism that was previously responsible for the cause event *C*. Indeed, one might think of an interventionist treatment of causation as explaining why Lewis' account with its somewhat counterintuitive similarity ordering works as well as it does -- Lewis' account works because his similarity ordering picks out roughly those relationships that are stable under interventions and hence exploitable for purposes of manipulation and control and, as a manipulability theory claims, it is just these relationships that are causal. This is not to say, however, that the two approaches always yield identical assessments of particular causal and counterfactual claims -- Hitchcock and Woodward, forthcoming and Woodward, forthcoming describe cases in which the two approaches diverge and in which the interventionist approach seems more satisfactory.[3].

11. The Scope of a Manipulability Theory

In the version of a manipulability theory considered under §6 above, causal claims are elucidated in terms of counterfactuals about what would happen under interventions. As we have seen, the notion of an intervention should be understood without reference to human action, and this permits formulation of a manipulability theory that applies to causal claims in situations in which manipulation by human beings

is not a practical possibility. Moreover, the counterfactual formulation allows us to make sense of causal claims in contexts in which interventions do not in fact occur and arguably even in cases in which they are causally impossible, as long as we have some principled basis for answers to questions about what *would* happen to the value of some variable *if* an intervention were to occur on another variable. Consider, for example, the (presumably true) causal claim (**G**):

> (**G**) The gravitational attraction of the moon causes the motion of the tidest.

Human beings cannot at present alter the attractive force exerted by the moon on the tides (e.g., by altering its orbit). More interestingly, it may well be that there is no physically possible process that will meet the conditions for an intervention on the moon's position with respect to the tides -- all possible processes that would alter the gravitational force exerted by the moon may be insufficiently "surgical". For example, it may very well be that any possible process that alters the position of the moon by altering the position of some other massive object will have an independent impact on the tides in violation of condition (**M2**) for an intervention. It is nonetheless arguable we have a principled basis in Newtonian mechanics and gravitational theory themselves for answering questions about what would happen if such a surgical intervention were to occur and that this is enough to vindicate the causal claim (**G**).

Although a properly formulated version of a manipulability theory will thus allow us to talk about causal relationships in some contexts in which interventions are not physically possible, there are plausible arguments that such theories do place some restrictions on which relationships qualify as causal. I conclude by considering several cases of this sort, which will also serve to bring out an additional distinctive feature of manipulability theories.

12. (Alleged) Causes That Are Unmanipulable for Logical, Conceptual, or Metaphysical Reasons

Several statisticians (e.g., Holland, 1986, Rubin, 1986) who advocate manipulationist or counterfactual accounts of causation have held that causal claims involving causes that are unmanipulable in principle are defective or lack a clear meaning -- they think of this conclusion as following directly from a manipulationist approach to causation. What is meant by an unmanipulable cause is not made very clear, but the examples discussed typically involve alleged causes (e.g., race, or membership in a particular species, or perhaps gender) for which we lack any clear conception of what would be involved in manipulating them or any basis for assessing what would happen under such a manipulation. Such cases contrast with the case involving (**G**) above, where the notion of manipulating the moon's orbit seems perfectly clear and well-defined, and the problem is simply that the world happens to be arranged in such a way that an intervention that produces such a change is not physically possible.

A sympathetic reconstruction of the position under discussion might go as follows. On a manipulationist account of causation, causes (whether we think of them as events, types of events, properties, facts, or what have you) must be representable by means of *variables* -- where this means, at a minimum, that it

must be possible for the cause to change or to assume different values. This is required if we are to have a well-defined notion of manipulating a cause and well-defined answers to counterfactual queries about what would happen if the cause were to be manipulated in some way -- matters which are central to what causal claims mean on any version of a manipulability theory worthy of the name. Philosophers tend to think of causes as properties or events but in many cases, it is straightforward to move back and forth between such talk and a representation in terms of variables, as we have been doing throughout this entry. For example, rather than saying that the impact of the baseball caused the window to shatter or that impacts of baseballs cause window shatterings, we may introduce two indicator variables -- *I* which takes the values 0 and 1 for {no impact, impact} and *S* which takes the values 0 and 1 for {no shattering, shattering} and use these variables to express the idea that whether or not the window shatters is counterfactually dependent on (interventions that determine) whether the impact occurs. Both *I* and *S* describe causes that are straightforwardly manipulable. However, for some putative causes, there may be no well-defined notion of change or variation in value and if so, a manipulability theory will not count these as genuine causes. For example, if it is metaphysically necessary that everything that exists is a physical object or if we lack any coherent conception of what it is for something to exist but to be non-physical, then there will be no well-defined notion of intervening to change whether something is a physical object. While there are true (and even lawful) generalizations about all physical objects, on a manipulability theory these will not describe causal relationships. Thus, although to the best of our knowledge, it is a law of nature that (**L**) no physical object can be accelerated from a velocity less than that of light to a velocity greater than light, (**L**) is not, according to a manipuability theory, a *causal* generalization.

Moreover, even with respect to variables that can take more than one value, the notion of an intervention or manipulation will not be well-defined if there is no well-defined notion of *changing* the values of that variable. Suppose that we introduce a variable "animal" which takes the values {lizard, kitten, raven}. By construction, this variable has more than one value, but if, as seems plausible, we have no coherent idea of what it is to change a raven into lizard or kitten, there will be no well-defined notion of an intervention for this variable and being an animal (or being a raven) will not be the sort of thing that can count as a bona-fide cause on a manipulability theory. The notion of changing the value of a variable seems to involve the idea of an alteration from one value of the variable to another in circumstances in which the very same system or entity can possess both values and this notion seems inapplicable to the case under discussion.

Some readers will take it to be intuitively obvious that being a raven can be a cause, e.g., of some particular organism's being black. Many standard theories of causation also endorse this conclusion, for example, if we are willing to assume it is a law that all ravens are black, then nomological theories of causation will support the claim (**R**):

> (**R**) Ravenness causes blackness.

Similarly, ravenness raises the probability of blackness and hence (**R**) qualifies as causal on probabilistic theories of causation, and depending on how the relevant similarity ordering is understood, (**R**) may also qualify as causal on a Lewis style counterfactual theory. If causal claims like (**R**) are true, it is an

important inadequacy in manipulability theories that they seem unable to capture such claims. By contrast, others will think that claims like (**R**) are, if not false, at least unclear and unperspicuous, and that it is a point in favor of manipulability theories that they explain why this is the case. Those who take this second view will think that claims like (**R**) should be replaced by claims that involve causes that are straightforwardly manipulable. For example, (**R**) might be replaced by a claim that identified the genetic factors and biochemical pathways that are responsible for raven pigmentation -- factors and pathways for which there is a well-defined notion of manipulation and which are such that if they were appropriately manipulated, this would lead to changes in pigmentation. Manipulability theorists like Rubin and Holland will think that such a replacement would be clearer and more perspicuous than the original claim (**R**). In any case, claims involving causes that are unmanipulable in the sense that we seem to lack any clear conception of what would be involved in manipulating them are one important sort of case in which a manipulability approach will diverge from many other standard theories of causation.

Consider an additional illustration of this general theme. Holland (1986) appeals to a manipulability theory of causation to argue that the following claim is fundamentally unclear.

> (**F**) Being female causes one to be discriminated against in hiring and/or salary

In contrast to the previous cases, the problem here is not so much that under all interpretations of the putative cause ("being female") we lack any clear idea of what it would be like to manipulate it, but rather that there are several rather different things that might be meant by manipulation of "being female" (which from the perspective of a manipulability theory is to say that there several quite different variables we might have in mind when we talk about being female as a cause) and the consequences for discrimination of manipulating each of these may be quite different. For example, (**F**) might be interpreted as claiming that a literal manipulation of gender, as in a sex change operation, that leaves an applicant's qualifications otherwise unchanged, will change expected salary or probability of hiring. Alternatively, and more plausibly, (**F**) might be interpreted as claiming that manipulation of a potential employer's *beliefs* about applicant's gender will change salary and hiring probability, in which case (**F**) would be more perspicuously expressed as the claim that employer beliefs about gender cause discrimination. Still another possible interpretation -- in fact what Holland claims one *ought* to mean by (**F**) -- is that differentials in salary and hiring between men and women would disappear (or at least be reduced substantially) under a regime in which various sorts of biased practices were effectively eliminated, presumably as the result of changes in law and custom. While I see no reason to follow Holland in thinking that this is the only legitimate interpretation of (**F**), it is plainly a legitimate interpretation. Moreover, Holland is also correct to think that this last hypothetical experiment which involves manipulating the legal and cultural framework in which discrimination takes place is a quite different experiment from an experiment involving manipulating gender itself or employee beliefs about gender and that each of these experiments is likely to lead to different outcomes. From the perspective of a manipulability theory, these different experiments thus correspond to different causal claims. As this example illustrates, part of the heuristic usefulness of a manipulability theory is that encourages us to clarify or disambiguate causal claims by explicitly distinguishing among different possible claims about the outcomes of hypothetical experiments that might be associated with them. That we can clarify the meaning of a causal claim in this way is just what we would expect if a manipulability account of

causation is correct.

Notes to Manipulability and Causation

Notes

1. As Pearl readily acknowledges, his work draws on a long tradition in econometrics of interpreting equations that express causal claims as claims about the outcomes of hypothetical experiments - see, e.g., Haavelmo, 1944.

2. For a related distinction, see Hitchcock, forthcoming.

3. More accurately, the interventionist account of type causation diverges from what seems to be the natural way of extending Lewis' theory to such causes. Consider a simple example discussed in Woodward, forthcoming. *C* is a deterministic direct (type) cause of *E* but also deterministically causes *E* indirectly by means of *n* causal routes that go through $C_1,\ldots,C_n$. Consider the counterfactual (1) "If $C_1,\ldots,C_n$ had not occurred, *E* would not have occurred". As explained above, any counterfactual theory will need to employ such counterfactuals to capture the notion of direct cause or causation along a route. On the interventionist account of the relationship between causal claims and counterfactuals, (1) is false, since under the assumption of the antecedent of (1), *C* will still occur and will cause *E*. Intuitively, this the correct assessment of (1). Under Lewis' theory, we have a choice between two different possible worlds that realize the antecedent of (1). In the first *C* occurs and each of the *n* links between *C* and $C_1,\ldots,C_n$ are broken. This requires *n* distinct miracles. In the second world, *C* fails to occur and hence $C_1,\ldots,C_n$ also fail to occur. This second world has less perfect match with the actual world than the first world, but involves only one miracle. At least for large *n*, Lewis' similarity ordering tells us that this second world is closer to the actual world. Thus (1) comes out true.

Gersonides

Perhaps no other medieval Jewish philosopher has been so maligned over the centuries as Gersonides (Levi ben Gerson, acronym Ralbag). Indeed, his major philosophical work, *Sefer Milhamot Ha-Shem* (*The War of the Lord*, 1329), was called "*Wars against the Lord*" by one of his opponents. Despite the vilification of his position, Gersonides emerges as one of the most significant and comprehensive thinkers in the medieval Jewish tradition. He has been constantly quoted (even if only to be criticized), and, through the works of Hasdai Crecas and others, Gersonides' ideas have influenced such thinkers as Gottfried Wilhelm Leibiniz and Benedict de Spinoza. This article will survey his major contributions to medieval philosophy.

1. Introduction

In the introduction to his recently completed translation of *Wars of the Lord*, Feldman suggests that the significance of Gersonides lies in his emphasis upon "religious rationalism in Judaism." According to Feldman, we see a man who "has taken seriously the fact that he has reason, who believes that this faculty is God-given, and who attempts to understand God with this instrument" (*Wars*, p. 52). Gersonides is the philosopher who attempted to show that philosophy and Torah, that reason and revelation are co-extensive; he is a philosophical optimist who believes that reason was fully competent to attain all the important and essential truths. Thus, according to Feldman, Gersonides is "a most vigorous and consistent defender of human reason in religion"(*Wars*, p. 53).

This trust is reflected in Gersonides' introductory remarks to *Wars*. There, Gersonides upholds the primacy of reason, attributing to Maimonides the position that "we must believe what reason has determined to be true. If the literal sense of the Torah differs from reason, it is necessary to interpret those passages in accordance with the demands of reason" (*Wars*, p. 98). Gersonides believes that reason and Torah cannot be in opposition: "if reason causes to affirm doctrines that are incompatible with the literal sense of Scripture, we are not prohibited by the Torah to pronounce the truth on these matters, for reason is not incompatible with the true understanding of the Torah" (*ibid.*). Thus reason is upheld as a criterion for achieving truth.

2. Biography

Gersonides left few letters and does not talk about himself in his writings; nor is his life discussed at great length by his contemporaries. Hence, what is known of his biography is sketchy at best. Levi ben Gerson was born in 1288 in Provence and may have lived for a time in Bagnol sur-Ceze. It is probable that his father was Gershom ben Salomon de Beziers, a notable mentioned in medieval histories. With the decline of Spanish Judaism in the thirteenth century, Provence quickly became the cultural center for Jewish intellectual activity. The popes in Avignon had a lenient policy toward the Jews, whose creative life flourished, particularly in philosophy and theology. Jewish philosophers did not have direct access to the works of Aristotle, but Provençal Jews learned of Aristotle through the commentaries of Averroes, the twelfth-century Spanish Muslim philosopher. By the end of the thirteenth century these commentaries had been translated from Arabic into Hebrew, and Averroes' thought, as well as that of Aristotle, was being integrated into the mainstream of Jewish philosophy.

Gersonides may have married a distant cousin; it is not known whether he had any offspring. Although Gersonides spoke Provençal, his works are all written in Hebrew, and all of his quotations from Averroes, Aristotle, and Moses Maimonides are in Hebrew as well. He may have had a reading knowledge of Latin; he appears to manifest an awareness of contemporary Scholastic discussions. He might, however, have learned of such discussions in oral conversations with his Christian contemporaries. Apart from several trips to Avignon, Gersonides most likely resided his entire life in Orange. There is some evidence that he may have followed the traditional occupation of his family, moneylending. He died on 20 April 1344.

In addition to Averroes and Aristotle, Gersonides was influenced by Moses Maimonides, his greatest Jewish philosophical predecessor. Gersonides' works can be seen as an attempt to integrate the teachings of Aristotle, as mediated through Averroes and Maimonides, with those of Judaism. In *Milhamot Ha-Shem* he laid down the general rule that "the Law cannot prevent us from considering to be true that which our reason urges us to believe." His adherence to this principle is reflected throughout his work.

3. Major Works

What distinguished Gersonides from his predecessors was his reliance upon and consummate knowledge

of mathematics, coupled with his belief in the accuracy of observations achieved by the use of good instruments. Because of this rootedness in empirical observation bolstered by mathematics, Gersonides believed that he had the tools to succeed where others had failed. Only when he has resolved the problems in astronomy does Gersonides apply their findings to theological cosmology. As we shall see, Gersonides' theology and astronomy are deeply involved with each other.

This realist stance is stated in the context of examining al-Bitruji's astronomical proposals. Gersonides' contention is that "no argument can nullify the reality that is perceived by the senses, for true opinion must follow reality but reality need not conform to opinion" (Goldstein, 1974, p. 24). That Gersonides clearly considered his own observations to be the ultimate test of his system is explicit from his attitude towards Ptolemy. The importance of empirical observation cannot be underestimated, he claims, and he values his own observations over those of others. "We did not find among our predecessors from Ptolemy to the present day observations that are helpful for this investigation except our own" (*Wars*, V.1.3, p. 27), he says in describing his method of collecting astronomical data. Often his observations do not agree with those of Ptolemy, and in those cases he tells us explicitly that he prefers his own. Gersonides lists the many inaccuracies he has found trying to follow Ptolemy's calculations. Having investigated the positions of the planets, for example, Gersonides encountered "confusion and disorder" which led him to deny several of Ptolemy's planetary principles (Goldstein, 1988, p. 386). He does warn his colleagues, however, to dissent from Ptolemy only after great diligence and scrutiny.

Gersonides' scientific works comprise mathematics and astronomy. His *Sefer Ma'aseh Hoshev* (*The Work of a Counter*, 1321) is concerned with arithmetical operations and uses of a symbolic notation for numerical variables. Gersonides' major scientific contributions were in astronomy; his works were known by his contemporaries and influenced later astronomers. His astronomical writings are contained primarily in book 5, part 1 of *Milhamot Ha-Shem*. In 136 chapters Gersonides reviews and criticizes astronomical theories of the day, compiles astronomical tables, and describes one of his astronomical inventions. This instrument, which he called *Megalle 'amuqqot* (*Revealer of Profundities*) and which was called *Bacullus Jacobi* (*Jacob's staff*) by his Christian contemporaries, was used to measure the heights of stars above the horizon. The astronomical parts of *Milhamot Ha-Shem* were translated into Latin during Gersonides' lifetime. One of the craters of the moon, *Rabbi Levi*, is named after him.

Gersonides was well known as a Halakhist, one who deals with the intricacies of Jewish law. From this respect, his greatest contribution to Judaica was in the area of biblical commentary. His commentary on the Book of Job, completed in 1325, proved to be one of his most popular works and was one of the earliest Hebrew books to be published (in Ferrara, 1477). The commentary, which complements book 4 of *Milhamot Ha-Shem*, is concerned with the problem of divine providence. Each of the characters in the Book of Job represents a different theory of divine providence; Gersonides' own position is a restatement of Elihu's theory that providence is not directed to particulars but rather to groups of individuals, or universals.

Gersonides also wrote a logical treatise, *Sefer Ha-heqesh Ha-yashar* (*On Valid Syllogisms*, 1319), in which he examines problems associated with Aristotle's modal logic as developed in the Prior Analytics. This treatise was translated into Latin at an early date, although Gersonides' name was not attached to it.

Gersonides' major philosophical work, *Milhamot Ha-Shem*, was completed in 1329; it had been twelve years in the making. In 1317 Gersonides began an essay on the problem of creation. This problem, which has vexed Jewish philosophers since Philo Judaeus, had recently received elaborate treatment by Maimonides. Gersonides was dissatisfied with Maimonides' discussion and proposed to reopen the issue. This project was soon laid aside, however, for he felt that it could not be adequately discussed without proper grounding in the issues of time, motion, and the infinite. By 1325 his manuscript had developed to include discussion not only of creation but also of immortality, divination, and prophecy. By 1328 it included a chapter on providence as well. Books 5 and 6 were completed, by Gersonides' own dating, by 1329.

As Isaac Husik has pointed out, Gersonides "has no use for rhetorical flourishes and figures of speech … the effect upon the reader is monotonous and wearisome." His style has been compared to that of Thomas Aquinas and even of Aristotle in its use of a precise, technical vocabulary which eschews examples. In contradistinction to Maimonides, who introduced allegory, metaphor, and imprecise language into his work to convey the ambiguity of the subject matter, Gersonides saw it as his function to elucidate the issues as clearly as possible. Gersonides is the first Jewish philosopher to use this analytic, scholastic method.

4. Major Themes in *Milhamot Ha-shem*

In the introduction to *Milhamot*, Gersonides specifies six questions which he hopes to examine: Is the rational soul immortal? What is the nature of prophecy? Does God know particulars? Does divine providence extend to individuals? What is the nature of astronomical bodies? Is the universe eternal or created? Each question occupies a separate book. Gersonides attempts to reconcile traditional Jewish beliefs with what he feels are the strongest points in Aristotle's philosophy. Although a synthesis of these systems is his ultimate goal, philosophy often wins out at the expense of theology.

Gersonides' attitude toward previous astronomers, coupled with his faith in human reason, are reflected in his discussion of creation. Maimonides went to great lengths to maintain that the topic of creation is beyond rational demonstration. Gersonides, on the other hand, devotes many chapters in *Milhamot* VI to proving that the Platonic theory of creation out of an eternal formless matter is rationally demonstrable. The question of whether the universe was created or had existed from eternity had been treated by Maimonides in an ambiguous manner; scholars still disagree over whether Maimonides ultimately upheld an Aristotelian, Platonic, or scriptural doctrine of creation. Gersonides' position is unambiguously Platonic. Gersonides argues that the world was created outside of time by a freely willing agent. He must then decide whether the world was engendered *ex nihilo* or out of a preexistent matter. Arguing that *ex nihilo* creation is incompatible with physical reality, he adopts a model drawn from Plato's *Timaeus*. Gersonides interprets the opening of Genesis to refer to two types of matter. *Geshem* is the primordial matter out of which the universe was created; not capable of motion or rest, it was characterized by negation and was inert and chaotic. This matter is identified with the primeval waters described in Genesis. *Homer* is prime matter, in the Aristotelian sense of a substratum always aligned with form. It

contains within itself the potentiality to receive forms but is not an ontologically independent entity. Gersonides compares this matter to darkness: just as darkness is the absence of light, this matter represents the absence of form or shape. On this basis Gersonides argues that the world was created out of an eternally preexistent matter.

Gersonides' cosmology forms the backdrop of the other books of *Milhamot*. His predecessor Maimonides had claimed that no valid inference can be drawn from the nature of the sublunar sphere to that of the superlunar sphere. Gersonides, however, rejects the metaphysical bite to the distinction, and argues that inasmuch as both spheres contain material elements, what we know about creation is based on astronomy, and astronomy is fundamentally no different a human science than physics. Astronomy can only be pursued as a science by "one who is both a mathematician and a natural philosopher, for he can be aided by both of these sciences and take from them whatever is needed to perfect his work" (*Wars*, V.1.1, p. 23). Gersonides sees the ultimate function of astronomy to understand God. Astronomy, he tells us, is instructive not only by virtue of its exalted subject matter, but also because of its utility in the other sciences. By studying the orbs and stars, we are led ineluctably to a fuller knowledge and appreciation of God. Astronomy thus functions as the underpinning of the rest of the work.

Gersonides' discussion of immortality of the soul in book 1 must be understood against the backdrop of a notoriously difficult passage in Aristotle's *On the Soul*, book 3, chapter 5 (430a22-25). In this passage Aristotle seems to postulate the existence of an active intellect which is separable from the passive intellect and which is primarily responsible for the intellectual activities of the human soul. But what is the relation between the active and passive intellects, and which, if either, is immortal? Gersonides states and rejects three positions that elucidate a version of the unity of intellect. The import of Gersonides' critique of his predecessors can be reduced to three main issues. From a theological perspective, it is clear that the doctrine of unity of intellect threatens the notion of personal immortality. For if all humans share the same intellect, then upon physical death, all that remains of the person is an unindividualized intellect. Epistemologically, the doctrine is unable to account for how it is that two (or more) knowers can entertain contrary items of knowledge; or, more stringently, how one person can be mistaken about something another person knows. And from a metaphysical perspective, the main problem is how to individuate this separate intellect when it is manifested in many individuals: for if it is individuated materially on the basis that individual bodies differ, then the substance is no longer incorporeal or separate. As Feldman has pointed out, on this theory an incorporeal substance is either a unique member of a species or is not a member of a species at all (*Wars*, I.4, p. 79).

Gersonides avoids these untoward consequences by adopting the position of Alexander of Aphrodisias. Gersonides agrees with Alexander of Aphrodisias that immortality consists in the intellectual perfection of the material intellect. He disagrees with Alexander, however, over the precise nature of this intellectual attainment. For Alexander (according to Gersonides) had claimed that immortality is achieved when the intellect acquires knowledge of the Agent Intellect (hence the term "acquired intellect" is introduced). Immortality is thus understood by Alexander to be a form of conjunction between the Agent and acquired intellects. "They [the followers of Alexander] maintain that the material intellect is capable of immortality and subsistence when it reaches that level of perfection where the objects of knowledge that it apprehends are themselves intellects, in particular the Agent

Intellect…[material intellect] is immortal when it is united with the Agent Intellect" (*Wars*, I.8, p. 170).

Gersonides rejects this notion of conjunction, however, and replaces it with a model of immortality according to which it is the content of knowledge of the acquired intellect that matters. When the content of the acquired intellect mirrors the rational ordering of the Agent Intellect, immortality is achieved. What is the content of this knowledge? The Agent Intellect must possess complete knowledge of the sublunary world; that is, it "contains a conception of the rational order obtaining in all individuals" (*Wars*, I.4, p. 136). The anti-Platonic tenor of this position is emphasized when Gersonides describes in more detail what it is that the Agent Intellect knows. For according to Gersonides, the knowledge of the Agent Intellect must be grounded in the domain of particulars. Thus Gersonides' position avoids the epistemological difficulties apparent in a realist ontology. Inasmuch as the material intellect reflects the knowledge inherent in the Agent Intellect, and inasmuch as this knowledge is grounded in particulars, it follows that humans can have knowledge of particulars; in this acquisition of knowledge lies immortality.

Books 2 to 4 focus on the relation between God and the world. The general problem is whether God's knowledge is limited to necessary states of affairs or extends to the domain of contingency as well. If the former, then God could not be said to have knowledge of humans, and so divine providence would not be efficacious. But if God does know contingents -- in particular, future contingent events -- then it would appear that human freedom is curtailed by God's prior knowledge of human actions. The problem of the apparent conflict between divine omniscience and human freedom was discussed by many medieval philosophers. Gersonides does not follow the majority opinion on this issue: rather than claim that God does know particulars and that this knowledge somehow does not affect human freedom, Gersonides argues that God knows particulars only in a certain sense. In an apparent attempt to mediate between the view of Aristotle, who said that God does not know particulars, and that of Maimonides, who said that he does, Gersonides holds that God knows particulars only insofar as they are ordered. That is, God knows that certain states of affairs are particular, but he does not know in what their particularity consists. God knows individual persons, for example, only through knowing the species humanity.

Whereas Maimonides claimed that God's knowledge does not render the objects of his knowledge necessary, Gersonides maintains that divine knowledge precludes contingency. To retain the domain of contingency, he adopts the one option open to him: namely, that God does not have prior knowledge of future contingents. According to Gersonides, God knows that certain states of affairs may or may not be actualized. But insofar as they are contingent states, he does not know which of the alternatives will be the case. For if God did know future contingents prior to their actualization, there could be no contingency in the world.

In book 2, in an attempt to explain how prophecies are possible in a system which denies the possibility of knowledge of future contingents, Gersonides claims that the prophet does not receive knowledge of particular future events; rather his knowledge is of a general form, and he must instantiate this knowledge with particular facts. What distinguishes prophets from ordinary persons is that the former are more attuned to receive these universal messages and are in a position to apply them to particular circumstances.

A further dilemma surrounds the doctrine of divine providence. If God does not have knowledge of future contingents, how can he be said to bestow providence on his creatures? This problem is discussed by Gersonides both in his commentary on Job and in book 4 of *Milhamot*. In both texts he argues that providence is general in nature; it primarily appertains to species and only incidentally to particulars of the species. God, for example, does not know the particular individual Levi ben Gerson and does not bestow particular providence on him. Rather, inasmuch as Levi ben Gerson is a member of the species humanity and the species philosopher, he is in a position to receive the providential care accorded to those groups.

For Gersonides, the issues of prophecy, omniscience and providence are developed against the backdrop of astrological determinism. Like many thinkers of the late Middle Ages, Gersonides had to confront two opposing sets of traditions: on the one hand, attacks by religious authorities (e.g. Augustine's attack in *City of God*; Maimonides' letters) on the grounds that astrology compromised human free will; on the other hand, the wide scale acceptance of astrology from the 12th century on. In the 12th and 13th centuries, most Jewish and Christian philosophers supported natural astrology, the view that the celestial bodies affect sublunar life and existence to some extent at least. That the sun and moon both affect natural cycles and events on earth is unequivocal and represents a classic paradigm of natural astrology. The calculations of natural astrology overlapped those of astronomy, and could be utilized for practical purposes such as fixing the calendar. According to astrologers, each planet and sign of the zodiac has its own character, power and attributes. Inasmuch as the characters of the planets and the signs of the zodiac are opposed to each other, they are engaged in a perpetual power struggle. Thus the position of the planets and their interrelation with the signs of the zodiac, regulate the fate of both individuals and nations. Astrological predictions could apply, then to both individuals as well as to the history of Israel and its place in universal history.

An attack upon astrology as a whole belonged to a much larger conflict, that between the roles of reason and faith. Thus, astrology should not be situated within the context of magic or the occult, but rather should be construed as a robust contender to science. Based on a precise scientific astronomy, astrology was a science accepted from the second to the seventeenth centuries. On the scientific level it prevailed almost uncontested until and including Newton.

5. Gersonides' Astrological Determinism

Even a summary reading of Gersonides' major philosophical work evinces an explicit "belief in" astrology. Gersonides develops his astral determinism in two contexts: in book II of *Wars* he interweaves astrological motifs into his discussion of divine providence and prophecy, while in Book V astrology occupies a central role in the context of his cosmological speculations. His major concern is the extent to which the stars and planets exerted an influence over human events in general, or more particularly, over those actions that entail human choice. Judicial astrology was based on the assumption that the entire world of nature was governed and directed by the movement of the heavens and the celestial bodies, and that man, as an animal naturally generated and living in the world of nature, was also naturally under

their rule.

Langermann emphasizes the teleological nature of astrology for Gersonides, its chief merit being its ability to provide "teleological explanations for the wide variety of stellar motions that are observed to take place" (*Wars*, Vol III, p. 506). This teleology is reflected in V.2 ch 7-9 where, after listing 27 problems raised by the heavenly bodies, Gersonides suggests that only astrological considerations can furnish satisfactory replies; it is astrology alone that can explain the connection between the two realms. It is worth noting that on this point, Gersonides disagrees with Maimonides over the ultimate purpose of the celestial bodies. For Maimonides it is not possible that a greater entity, the heavens, would exist for the sake of the sublunar universe. Gersonides disagrees, maintaining that it is not inappropriate that the more noble exist for the less noble. The stars, he argues, exist for the sake of things in the sublunar world (*Wars*, V.2.3, p. 194). More explicitly, the heavenly bodies are designed for the benefit of sublunar existence, and they guarantee the perpetuation of life on earth.

This teleology is spelled out in *Milhamot* II, in which Gersonides is concerned to explain how divine knowledge operates, and to what extent divine foreknowledge of future contingents affects human choice. His major thesis is that divine knowledge is predicated to a great extent upon knowledge of the heavenly bodies, which bodies are in turn "systematically directed toward his [man's] preservation and guidance so that all his activities and thoughts are ordered by them" (*Wars*, II.2, p. 33). In support of this teleological cosmology, Gersonides presents an extensive argument to the effect that the celestial bodies have a purpose. On the basis of this argument Gersonides concludes that from the perspective of the teleological structure of the universe, we can understand why the heavenly bodies behave the way they do. This teleology is reflected by a "law, order and rightness" in the universe, implying the existence of an intellect that orders the nature of things: "you see that the domain of the spheres provides, in the best way possible, for the sub-lunar world" (*Wars*, V.2.5, p. 137).

As we have seen, the existence of a connection between celestial and terrestrial events was admitted by most everybody, but not everybody agreed on the nature of this connection. Gersonides as well must account for the type of relation obtaining between celestial and terrestrial events. Having articulated the ordering power of the astral bodies, Gersonides describes in *Milhamot* V.3 the separate intellects and the spheres that they move. The main characteristic of the astral bodies is their luminosity (*nitzutz*). This luminosity affects their actions and effects (*Wars*, V.2.3, p. 137). Gersonides is very much aware of the problem of accounting for how the astral bodies can affect actions at a distance. The sun, for example, functions as a paradigm for action at a distance. Once we understand, Gersonides claims, how the activity of heating reaches earth from the sun, we can understand how the particular activities of the other stars reach the sublunar realm as well. By explaining the efficient cause as the light or radiation of the stars, Gersonides can account for weak or strong effects. As Langerman has pointed out, Gersonides' account furnishes the basis for the introduction of astrological causation into natural philosophy.

In *Milhamot* V.2.8 Gersonides lays out six astrological principles that affect his general cosmological scheme. These can be summarized as follows. First, each astral body exercises a different influence specific to it. Second, astral influence depends upon its position in the zodiac (*galgal hamazalot*). Third, the longer a star stays in one place in the zodiac, the greater its effect because of the strength of its

luminosity. Fourth, astral influence is dependent upon its inclination to the north or to the south; its effect will be strongest when it is in the middle, as evidenced by the sun, whose heat is strongest when it is at the Tropic of Cancer as opposed to being at the Tropic of Capricorn. Fifth, the greater the radiation or luminosity of a star, the stronger its influence. And finally, the closer to earth a star is, the stronger will be its influence (*Wars*, V.2.8, p. 207-8). These principles function as the underpinnings of his general astronomy as well.

In light of the original problems posed by astrology above, let me propose that the most important piece of Levi's astrology is what Langermann calls the variety of the heavens (*ribbui hayahasim*). Gersonides must be able to account for individual variety in the sublunar realm. Inasmuch as stellar radiation is the means by which stellar influences are conveyed, the wide variety of mixtures of stellar radiation guarantees a sufficient variety of "influences" on terrestrial processes. The movers emanate from God who is construed as the "First Separate Intellect" (*Wars*, V.3.8, p. 272). They are ordered in a rational system that governs the sublunar domain. If there were no one first intellect, Gersonides argues, the rational order we see in the heavens would be the result of chance, which is unacceptable. The agent intellect thus functions as the link between these celestial bodies and human affairs. The kinds of information it transmits are of an astronomical type, as evidenced in the following example: "it [the agent intellect] knows how many revolutions of the sun, or of the diurnal sphere, or of any other sphere [have transpired] from the time at which someone, who falls under a particular pattern, had a particular level of good or ill fortune…" (*Wars*, II.6, p. 64). The agent intellect serves as the repository of information communicated by the heavenly bodies. The patterns revealed in this communication between agent intellect and diviner (astrologer, prophet) are from the heavenly bodies which themselves are endowed with intellects and so "apprehend the pattern that derives from them." Each mover apprehends the order deriving from the heavenly body it moves, and not patterns that emanate from other heavenly bodies. As a result, the imaginative faculty receives the "pattern inherent in the intellects of the heavenly bodies from the influence deriving from them. This influence derives from the position of the heavenly bodies "by the ascendent degree or the dominant planet [in a particular zodiacal position]" (*Wars*, II.6, p. 64). However, inasmuch as the heavenly bodies do not jointly cooperate with one another (*lo yishtatfu*) in this process, it is possible for the communication to be misconstrued.

Of course, as we all know, astrologers often err in their predictions. Astrological errors can be due to several factors. In general, Gersonides claims, we know very little of the order of the heavenly bodies. "In general, it is impossible for man to know the [complete] truth of the order of the sublunar world. This is nicely illustrated in astrology, where frequently false predictions are made. All the more so is it impossible for man to know the general order of the sublunar world by means of its causes so that his knowledge would be perfect" (*Wars*, I.12, p. 219). In some cases, the information is not transmitted clearly. Why is it that certain communications are received more clearly than others? A constitutionally perfect imaginative faculty receives information from both dominant and weak heavenly bodies. By 'weak', Gersonides means that certain celestial bodies are too weak both to bring about events on earth as well as to transmit information about these events. Hence he concludes that information about the future emanates "from the dominant body in the particular proper face (*panim*) in which it has dominance but not from any of the attending planets (*ha-meshartim*)" (*Wars*, II.7, pp. 69-70). But to constitutionally imperfect imaginative faculties, the information received is only from the dominant heavenly bodies.

Hence the overall quality of the information received will differ in the two cases. More specifically, because of the difficulty of obtaining the necessary positions of these bodies by observation, astrologers are often unable to verify their data. Furthermore, since the zodiacal position of a heavenly body at any given time is only repeated once in many thousands of years, astrologers have no access to the repeatability of those events that would be required to verify their knowledge. Furthermore, humans simply do not have sufficient knowledge about the heavenly bodies.

The final cause for error has to do with human free will: as we have seen above, our intellect and choice "have the power to move us contrary to that which is determined by the heavenly bodies" (*Wars*, II.2, p. 34). Although he admits that on occasion human choice is able to contravene the celestial bodies, nevertheless this intervention is rare, and true contingency is a rare state of affairs indeed in Gersonides' ontology. Gersonides presents an argument to show that human choice guided by reason can subvert the celestial bodies despite their general ordering of our lives. The heavenly bodies can order human affairs either by virtue of their difference of position in the heavens, or from the difference of the bodies among themselves. Astral bodies, however, will affect different individuals in different ways; they can also affect an individual differently at different times; and finally, two or more bodies can affect a single individual, resulting in multiple influences that can have contrary effects, echoing the scholastic phrase, "*sapiens dominabitur astris* [the wise man will be ruled by the stars]". Gersonides notes that humans can contravene these effects: God has provided humans with "the intellectual capacity (*sekhel ba'al takhlit*) that enables us both to act contrary to what has been ordered by the heavenly bodies and to correct, as far as possible, the [astrally ordained] misfortunes that befall us" (*Wars*, II.2, p. 35). Nevertheless, he assures us that whatever happens by chance is "determined and ordered according to this type of determinateness and order" (*Wars*, II.2, p. 34). Outdoing even Plato's hierarchical structuring in *Republic* IV, Gersonides argues that the ultimate perfection and ordering of society is due to astrological influence.

The commensurability of the motion of heavenly bodies raises an additional concern, having to do with the uniqueness of individual beings and the doctrine of eternal return. Gersonides' immediate 13th century predecessors Shem-Tov ibn Falaquera and Judah ben Solomon ha-Cohen discussed this issue against the backdrop of Aristotle's *Gen. Animalia*. In *Gen. Animalia,* Aristotle had established a connection between the life spans and gestations periods of animals and the revolutions of the sun and moon (*Gen. Anim.,* IV.10, 777b17-778a10). Thus the revolutions of the sun measure not only time but also produce the alternating periods of growth and decay. Eschatological predictions are thus tied to the cyclicity of the heavenly bodies. Gersonides did not [to our knowledge] indulge in eschatological and millennial predictions. In fact, Gersonides wrote only one astrological text that has survived, a prognostication based on the conjunction of Saturn and Jupiter to take place in March 1345. Gersonides himself died in 1344, a year before the event in question. As Goldstein has demonstrated, this conjunction was predicted already by Ibn Ezra, and repeated by Abraham Bar Hiyya in his *Megillat ha-Megalleh* where the conjunction was associated with a date of messianic significance that would supposedly take effect in 1358 (Goldstein, 1990, p. 3). The conjunction was codified by Levi ben Abraham ben Hayyim in his encyclopedia *Livyat Hen*, indicating an awareness in the Jewish community of the messianic significance of this conjunction. According to North, Ibn Ezra was the earliest scholar to record one of the seven methods for the setting up of the astrological houses; Gersonides then computed the astrological houses for the prognostication of 1345 according to Ibn Ezra's method. (See North, 1986,

p. 25.) Goldstein suggests that as the date 1345 approached, the Papal court might have become interested as well in the conjunction. We do know that Gersonides' text was translated into Latin with the aid of his brother shortly after Gersonides' death in 1344.

In his prognostication, Gersonides predicts that there will be "extraordinary evil with many wars, visions and miraculous signs;" "Diseases and death, and the evil will endure for a long time;" "the absence of good, pleasure and happiness for most of the inhabited world;" "the spilling of much blood and increasing enmity, jealousy, strife, famine, various diseases, drought and dearth" (Goldstein, 1990). The Black Death, which arrived in Europe in 1347, was thus provided with numerous astrological credentials. The official statement of the medical faculty of the University of Paris, presented to the king in 1348, reported on the conjunction of Saturn and Jupiter in the house of Aquarius on 20 March 1345, which was seen to spread "death and disaster". It is not hard to see how the conjunction of 1345 came to be associated with the Black Death.

6. Conclusion

Gersonides' philosophical ideas went against the grain of traditional Jewish thought. Gersonides reflects the following characteristics: first, his writings demonstrate a fundamental interplay and harmony between astrological and theological beliefs. It is clear that the appeal of astrology lay in the fact that it offered useful information, while it looked and operated like a science. Even the critics of astrology had to agree that the heavens exerted a real influence upon terrestrial events. The complexity of the rules of astrology and internal disagreement among its followers served to increase the respect accorded to the science. Failures did not cause the astrologer to lose faith, just as failures among modern physicists do not lead to loss of faith in science. Gersonides believed that life on earth had a meaning, and that terrestrial events had an order. Astrology was a means of ascertaining that meaning. Gersonides' views on prophecy, providence, free-will and evil reflected ingredients of this philosophical determinism. Whereas his commentaries occupied a central place in Jewish theology, his philosophical work was rejected. Jewish philosophers such as Hasdai Crescas and Isaac Abrabanel felt obliged to subject his works to lengthy criticism. Only in recent years has Gersonides received his rightful place in the history of philosophy. As scholars have rediscovered his thought and have made his corpus available to a modern audience, Gersonides is once again appreciated as an insightful, ruthlessly consistent philosopher.

Bibliography

Principal Works

- *Sefer Ha-heqesh Ha-yashar* (On Valid Syllogisms, written 1319); translated into Latin as *Liber Syllogismi Recti*.
- *Sefer Ma'aseh Hoshev* (*The Work of a Counter*, written 1321; edited and translated into German by Gerson Lange (Frankfurt am Main: Golde, 1909).

- *Perush 'al Sefer lyob* (*Commentary on Job*, written 1325; Ferrara, 1477).
- *Sefer Milhamot Ha-Shem* (*The Wars of the Lord*, written 1329; Riva di Trento, 1560; Leipzig, 1866; Berlin, 1923).
- *Perush 'al Sefer Ha-Torah* (*Commentary on the Pentateuch*, written 1329-1338; Venice, 1547; Jerusalem, 1967).

Editions in English

- *The Commentary of Levi ben Gerson on the Book of Job*, translated by Abraham L. Lassen. New York: Bloch, 1946.
- *Providence and the Philosophy of Gersonides*, translated by David Bleich. New York: Yeshiva University Press, 1973.

Computer Ethics: Basic Concepts and Historical Overview

Computer ethics is a new branch of ethics that is growing and changing rapidly as computer technology also grows and develops. The term "computer ethics" is open to interpretations both broad and narrow. On the one hand, for example, computer ethics might be understood very narrowly as the efforts of professional philosophers to apply traditional ethical theories like utilitarianism, Kantianism, or virtue ethics to issues regarding the use of computer technology. On the other hand, it is possible to construe computer ethics in a very broad way to include, as well, standards of professional practice, codes of conduct, aspects of computer law, public policy, corporate ethics--even certain topics in the sociology and psychology of computing.

In the industrialized nations of the world, the "information revolution" already has significantly altered many aspects of life -- in banking and commerce, work and employment, medical care, national defense, transportation and entertainment. Consequently, information technology has begun to affect (in both good and bad ways) community life, family life, human relationships, education, freedom, democracy, and so on (to name a few examples). Computer ethics in the broadest sense can be understood as that branch of applied ethics which studies and analyzes such social and ethical impacts of information technology.

In recent years, this robust new field has led to new university courses, conferences, workshops, professional organizations, curriculum materials, books, articles, journals, and research centers. And in the age of the world-wide-web, computer ethics is quickly being transformed into "global information ethics".

---

1. Some Historical Milestones

1940s and 1950s

Computer ethics as a field of study has its roots in the work of MIT professor Norbert Wiener during World War II (early 1940s), in which he helped to develop an antiaircraft cannon capable of shooting down fast warplanes. The engineering challenge of this project caused Wiener and some colleagues to create a new field of research that Wiener called "cybernetics" -- the science of information feedback systems. The concepts of cybernetics, when combined with digital computers under development at that time, led Wiener to draw some remarkably insightful ethical conclusions about the technology that we now call ICT (information and communication technology). He perceptively foresaw revolutionary social and ethical consequences. In 1948, for example, in his book *Cybernetics: or control and communication in the animal and the machine*, he said the following:

> It has long been clear to me that the modern ultra-rapid computing machine was in principle an ideal central nervous system to an apparatus for automatic control; and that its input and output need not be in the form of numbers or diagrams. It might very well be, respectively, the readings of artificial sense organs, such as photoelectric cells or thermometers, and the performance of motors or solenoids ... . we are already in a position to construct artificial machines of almost any degree of elaborateness of performance. Long before Nagasaki and the public awareness of the atomic bomb, it had occurred to me that we were here in the presence of another social potentiality of unheard-of importance for good and for evil. (pp. 27-28)

In 1950 Wiener published his monumental book, *The Human Use of Human Beings*. Although Wiener did not use the term "computer ethics" (which came into common use more than two decades later), he laid down a comprehensive foundation which remains today a powerful basis for computer ethics research and analysis.

Wiener's book included (1) an account of the purpose of a human life, (2) four principles of justice, (3) a powerful method for doing applied ethics, (4) discussions of the fundamental questions of computer ethics, and (5) examples of key computer ethics topics. [Wiener 1950/1954, see also Bynum 1999]

Wiener's foundation of computer ethics was far ahead of its time, and it was virtually ignored for

decades. On his view, the integration of computer technology into society will eventually constitute the remaking of society -- the "second industrial revolution". It will require a multi-faceted process taking decades of effort, and it will radically change everything. A project so vast will necessarily include a wide diversity of tasks and challenges. Workers must adjust to radical changes in the work place; governments must establish new laws and regulations; industry and businesses must create new policies and practices; professional organizations must develop new codes of conduct for their members; sociologists and psychologists must study and understand new social and psychological phenomena; and philosophers must rethink and redefine old social and ethical concepts.

1960s

In the mid 1960s, Donn Parker of SRI International in Menlo Park, California began to examine unethical and illegal uses of computers by computer professionals. "It seemed," Parker said, "that when people entered the computer center they left their ethics at the door." [See Fodor and Bynum, 1992] He collected examples of computer crime and other unethical computerized activities. He published "Rules of Ethics in Information Processing" in *Communications of the ACM* in 1968, and headed the development of the first Code of Professional Conduct for the Association for Computing Machinery (eventually adopted by the ACM in 1973). Over the next two decades, Parker went on to produce books, articles, speeches and workshops that re-launched the field of computer ethics, giving it momentum and importance that continue to grow today. Although Parker's work was not informed by a general theoretical framework, it is the next important milestone in the history of computer ethics after Wiener. [See Parker, 1968; Parker, 1979; and Parker et al., 1990.]

1970s

During the late 1960s, Joseph Weizenbaum, a computer scientist at MIT in Boston, created a computer program that he called ELIZA. In his first experiment with ELIZA, he scripted it to provide a crude imitation of "a Rogerian psychotherapist engaged in an initial interview with a patient". Weizenbaum was shocked at the reactions people had to his simple computer program: some practicing psychiatrists saw it as evidence that computers would soon be performing automated psychotherapy. Even computer scholars at MIT became emotionally involved with the computer, sharing their intimate thoughts with it. Weizenbaum was extremely concerned that an "information processing model" of human beings was reinforcing an already growing tendency among scientists, and even the general public, to see humans as mere machines. Weizenbaum's book, *Computer Power and Human Reason* [Weizenbaum, 1976], forcefully expresses many of these ideas. Weizenbaum's book, plus the courses he offered at MIT and the many speeches he gave around the country in the 1970s, inspired many thinkers and projects in computer ethics.

In the mid 1970s, Walter Maner (then of Old Dominion University in Virginia; now at Bowling Green State University in Ohio) began to use the term "computer ethics" to refer to that field of inquiry dealing with ethical problems aggravated, transformed or created by computer technology. Maner offered an experimental course on the subject at Old Dominion University. During the late 1970s (and indeed into

the mid 1980s), Maner generated much interest in university-level computer ethics courses. He offered a variety of workshops and lectures at computer science conferences and philosophy conferences across America. In 1978 he also self-published and disseminated his *Starter Kit in Computer Ethics*, which contained curriculum materials and pedagogical advice for university teachers to develop computer ethics courses. The *Starter Kit* included suggested course descriptions for university catalogs, a rationale for offering such a course in the university curriculum, a list of course objectives, some teaching tips and discussions of topics like privacy and confidentiality, computer crime, computer decisions, technological dependence and professional codes of ethics. Maner's trailblazing course, plus his *Starter Kit* and the many conference workshops he conducted, had a significant impact upon the teaching of computer ethics across America. Many university courses were put in place because of him, and several important scholars were attracted into the field.

1980s

By the 1980s, a number of social and ethical consequences of information technology were becoming public issues in America and Europe: issues like computer-enabled crime, disasters caused by computer failures, invasions of privacy via computer databases, and major law suits regarding software ownership. Because of the work of Parker, Weizenbaum, Maner and others, the foundation had been laid for computer ethics as an academic discipline. (Unhappily, Wiener's ground-breaking achievements were essentially ignored.) The time was right, therefore, for an explosion of activities in computer ethics.

In the mid-80s, James Moor of Dartmouth College published his influential article "What Is Computer Ethics?" (see discussion below) in *Computers and Ethics*, a special issue of the journal *Metaphilosophy* [Moor, 1985]. In addition, Deborah Johnson of Rensselaer Polytechnic Institute published *Computer Ethics* [Johnson, 1985], the first textbook -- and for more than a decade, the defining textbook -- in the field. There were also relevant books published in psychology and sociology: for example, Sherry Turkle of MIT wrote *The Second Self* [Turkle, 1984], a book on the impact of computing on the human psyche; and Judith Perrolle produced *Computers and Social Change: Information, Property and Power* [Perrolle, 1987], a sociological approach to computing and human values.

In the early 80s, the present author (Terrell Ward Bynum) assisted Maner in publishing his *Starter Kit in Computer Ethics* [Maner, 1980] at a time when most philosophers and computer scientists considered the field to be unimportant [See Maner, 1996]. Bynum furthered Maner's mission of developing courses and organizing workshops, and in 1985, edited a special issue of *Metaphilosophy* devoted to computer ethics [Bynum, 1985]. In 1991 Bynum and Maner convened the first international multidisciplinary conference on computer ethics, which was seen by many as a major milestone of the field. It brought together, for the first time, philosophers, computer professionals, sociologists, psychologists, lawyers, business leaders, news reporters and government officials. It generated a set of monographs, video programs and curriculum materials [see van Speybroeck, July 1994].

1990s

During the 1990s, new university courses, research centers, conferences, journals, articles and textbooks appeared, and a wide diversity of additional scholars and topics became involved. For example, thinkers like Donald Gotterbarn, Keith Miller, Simon Rogerson, and Dianne Martin -- as well as organizations like Computer Professionals for Social Responsibility, the Electronic Frontier Foundation, ACM-SIGCAS -- spearheaded projects relevant to computing and professional responsibility. Developments in Europe and Australia were especially noteworthy, including new research centers in England, Poland, Holland, and Italy; the ETHICOMP series of conferences led by Simon Rogerson and the present author; the CEPE conferences founded by Jeroen van den Hoven; and the Australian Institute of Computer Ethics headed by Chris Simpson and John Weckert.

These important developments were significantly aided by the pioneering work of Simon Rogerson of De Montfort University (UK), who established the Centre for Computing and Social Responsibility there. In Rogerson's view, there was need in the mid-1990s for a "second generation" of computer ethics developments:

> The mid-1990s has heralded the beginning of a second generation of Computer Ethics. The time has come to build upon and elaborate the conceptual foundation whilst, in parallel, developing the frameworks within which practical action can occur, thus reducing the probability of unforeseen effects of information technology application [Rogerson, Spring 1996, 2; Rogerson and Bynum, 1997].

2. Defining the Field of Computer Ethics

From the 1940s through the 1960s, therefore, there was no discipline known as "computer ethics" (notwithstanding the work of Wiener and Parker). However, beginning with Walter Maner in the 1970s, active thinkers in computer ethics began trying to delineate and define computer ethics as a field of study. Let us briefly consider five such attempts:

When he decided to use the term "computer ethics" in the mid-70s, Walter Maner defined the field as one which examines "ethical problems aggravated, transformed or created by computer technology". Some old ethical problems, he said, are made worse by computers, while others are wholly new because of information technology. By analogy with the more developed field of medical ethics, Maner focused attention upon applications of traditional ethical theories used by philosophers doing "applied ethics" -- especially analyses using the utilitarian ethics of the English philosophers Jeremy Bentham and John Stuart Mill, or the rationalist ethics of the German philosopher Immanual Kant.

In her book, *Computer Ethics*, Deborah Johnson [1985] defined the field as one which studies the way in which computers "pose new versions of standard moral problems and moral dilemmas, exacerbating the old problems, and forcing us to apply ordinary moral norms in uncharted realms," [Johnson, page 1]. Like Maner before her, Johnson recommended the "applied ethics" approach of using procedures and concepts from utilitarianism and Kantianism. But, unlike Maner, she did not believe that computers create wholly new moral problems. Rather, she thought that computers gave a "new twist" to old ethical

issues which were already well known.

James Moor's definition of computer ethics in his article "What Is Computer Ethics?" [Moor, 1985] was much broader and more wide-ranging than that of Maner or Johnson. It is independent of any specific philosopher's theory; and it is compatible with a wide variety of methodological approaches to ethical problem-solving. Over the past decade, Moor's definition has been the most influential one. He defined computer ethics as a field concerned with "policy vacuums" and "conceptual muddles" regarding the social and ethical use of information technology:

> A typical problem in computer ethics arises because there is a policy vacuum about how computer technology should be used. Computers provide us with new capabilities and these in turn give us new choices for action. Often, either no policies for conduct in these situations exist or existing policies seem inadequate. A central task of computer ethics is to determine what we should do in such cases, that is, formulate policies to guide our actions.... One difficulty is that along with a policy vacuum there is often a conceptual vacuum. Although a problem in computer ethics may seem clear initially, a little reflection reveals a conceptual muddle. What is needed in such cases is an analysis that provides a coherent conceptual framework within which to formulate a policy for action [Moor, 1985, 266].

Moor said that computer technology is genuinely revolutionary because it is "logically malleable":

> Computers are logically malleable in that they can be shaped and molded to do any activity that can be characterized in terms of inputs, outputs and connecting logical operations....Because logic applies everywhere, the potential applications of computer technology appear limitless. The computer is the nearest thing we have to a universal tool. Indeed, the limits of computers are largely the limits of our own creativity [Moor, 1985, 269]

According to Moor, the computer revolution is occurring in two stages. The first stage was that of "technological introduction" in which computer technology was developed and refined. This already occurred in America during the first forty years after the Second World War. The second stage -- one that the industrialized world has only recently entered -- is that of "technological permeation" in which technology gets integrated into everyday human activities and into social institutions, changing the very meaning of fundamental concepts, such as "money", "education", "work", and "fair elections".

Moor's way of defining the field of computer ethics is very powerful and suggestive. It is broad enough to be compatible with a wide range of philosophical theories and methodologies, and it is rooted in a perceptive understanding of how technological revolutions proceed. Currently it is the best available definition of the field.

Nevertheless, there is yet another way of understanding computer ethics that is also very helpful--and

compatible with a wide variety of theories and approaches. This "other way" was the approach taken by Wiener in 1950 in his book *The Human Use of Human Beings*, and Moor also discussed it briefly in "What Is Computer Ethics?" [1985]. According to this alternative account, computer ethics identifies and analyzes the impacts of information technology upon human values like health, wealth, opportunity, freedom, democracy, knowledge, privacy, security, self-fulfillment, and so on. This very broad view of computer ethics embraces applied ethics, sociology of computing, technology assessment, computer law, and related fields; and it employs concepts, theories and methodologies from these and other relevant disciplines [Bynum, 1993]. The fruitfulness of this way of understanding computer ethics is reflected in the fact that it has served as the organizing theme of major conferences like the National Conference on Computing and Values (1991), and it is the basis of recent developments such as Brey's "disclosive computer ethics" methodology [Brey 2000] and the emerging research field of "value-sensitive computer design". (See, for example, [Friedman, 1997], [Friedman and Nissenbaum, 1996], [Introna and Nissenbaum, 2000].)

In the 1990s, Donald Gotterbarn became a strong advocate for a different approach to defining the field of computer ethics. In Gotterbarn's view, computer ethics should be viewed as a branch of professional ethics, which is concerned primarily with standards of practice and codes of conduct of computing professionals:

> There is little attention paid to the domain of professional ethics -- the values that guide the day-to-day activities of computing professionals in their role as professionals. By computing professional I mean anyone involved in the design and development of computer artifacts... The ethical decisions made during the development of these artifacts have a direct relationship to many of the issues discussed under the broader concept of computer ethics [Gotterbarn, 1991].

With this professional-ethics definition of computer ethics in mind, Gotterbarn has been involved in a number of related activities, such as co-authoring the third version of the ACM Code of Ethics and Professional Conduct and working to establish licensing standards for software engineers [Gotterbarn, 1992; Anderson, et al., 1993; Gotterbarn, et al., 1997].

3. Example Topics in Computer Ethics

No matter which re-definition of computer ethics one chooses, the best way to understand the nature of the field is through some representative examples of the issues and problems that have attracted research and scholarship. Consider, for example, the following topics:

(See also the wide range of topics included in the recent anthology [Spinello and Tavani, 2001].)

3.1 Computers in the Workplace

As a "universal tool" that can, in principle, perform almost any task, computers obviously pose a threat to jobs. Although they occasionally need repair, computers don't require sleep, they don't get tired, they don't go home ill or take time off for rest and relaxation. At the same time, computers are often far more efficient than humans in performing many tasks. Therefore, economic incentives to replace humans with computerized devices are very high. Indeed, in the industrialized world many workers already have been replaced by computerized devices -- bank tellers, auto workers, telephone operators, typists, graphic artists, security guards, assembly-line workers, and on and on. In addition, even professionals like medical doctors, lawyers, teachers, accountants and psychologists are finding that computers can perform many of their traditional professional duties quite effectively.

The employment outlook, however, is not all bad. Consider, for example, the fact that the computer industry already has generated a wide variety of new jobs: hardware engineers, software engineers, systems analysts, webmasters, information technology teachers, computer sales clerks, and so on. Thus it appears that, in the short run, computer-generated unemployment will be an important social problem; but in the long run, information technology will create many more jobs than it eliminates.

Even when a job is not eliminated by computers, it can be radically altered. For example, airline pilots still sit at the controls of commercial airplanes; but during much of a flight the pilot simply watches as a computer flies the plane. Similarly, those who prepare food in restaurants or make products in factories may still have jobs; but often they simply push buttons and watch as computerized devices actually perform the needed tasks. In this way, it is possible for computers to cause "de-skilling" of workers, turning them into passive observers and button pushers. Again, however, the picture is not all bad because computers also have generated new jobs which require new sophisticated skills to perform -- for example, "computer assisted drafting" and "keyhole" surgery.

Another workplace issue concerns health and safety. As Forester and Morrison point out [Forester and Morrison, 140-72, Chapter 8], when information technology is introduced into a workplace, it is important to consider likely impacts upon health and job satisfaction of workers who will use it. It is possible, for example, that such workers will feel stressed trying to keep up with high-speed computerized devices -- or they may be injured by repeating the same physical movement over and over -- or their health may be threatened by radiation emanating from computer monitors. These are just a few of the social and ethical issues that arise when information technology is introduced into the workplace.

3.2 Computer Crime

In this era of computer "viruses" and international spying by "hackers" who are thousands of miles away, it is clear that computer security is a topic of concern in the field of Computer Ethics. The problem is not so much the physical security of the hardware (protecting it from theft, fire, flood, etc.), but rather "logical security", which Spafford, Heaphy and Ferbrache [Spafford, et al, 1989] divide into five aspects:

1. Privacy and confidentiality
2. Integrity -- assuring that data and programs are not modified without proper authority
3. Unimpaired service
4. Consistency -- ensuring that the data and behavior we see today will be the same tomorrow
5. Controlling access to resources

Malicious kinds of software, or "programmed threats", provide a significant challenge to computer security. These include "viruses", which cannot run on their own, but rather are inserted into other computer programs; "worms" which can move from machine to machine across networks, and may have parts of themselves running on different machines; "Trojan horses" which appear to be one sort of program, but actually are doing damage behind the scenes; "logic bombs" which check for particular conditions and then execute when those conditions arise; and "bacteria" or "rabbits" which multiply rapidly and fill up the computer's memory.

Computer crimes, such as embezzlement or planting of logic bombs, are normally committed by trusted personnel who have permission to use the computer system. Computer security, therefore, must also be concerned with the actions of trusted computer users.

Another major risk to computer security is the so-called "hacker" who breaks into someone's computer system without permission. Some hackers intentionally steal data or commit vandalism, while others merely "explore" the system to see how it works and what files it contains. These "explorers" often claim to be benevolent defenders of freedom and fighters against rip-offs by major corporations or spying by government agents. These self-appointed vigilantes of cyberspace say they do no harm, and claim to be helpful to society by exposing security risks. However every act of hacking is harmful, because any known successful penetration of a computer system requires the owner to thoroughly check for damaged or lost data and programs. Even if the hacker did indeed make no changes, the computer's owner must run through a costly and time-consuming investigation of the compromised system [Spafford, 1992].

3.3 Privacy and Anonymity

One of the earliest computer ethics topics to arouse public interest was privacy. For example, in the mid-1960s the American government already had created large databases of information about private citizens (census data, tax records, military service records, welfare records, and so on). In the US Congress, bills were introduced to assign a personal identification number to every citizen and then gather all the government’s data about each citizen under the corresponding ID number. A public outcry about "big-

brother government" caused Congress to scrap this plan and led the US President to appoint committees to recommend privacy legislation. In the early 1970s, major computer privacy laws were passed in the USA. Ever since then, computer-threatened privacy has remained as a topic of public concern. The ease and efficiency with which computers and computer networks can be used to gather, store, search, compare, retrieve and share personal information make computer technology especially threatening to anyone who wishes to keep various kinds of "sensitive" information (e.g., medical records) out of the public domain or out of the hands of those who are perceived as potential threats. During the past decade, commercialization and rapid growth of the internet; the rise of the world-wide-web; increasing "user-friendliness" and processing power of computers; and decreasing costs of computer technology have led to new privacy issues, such as data-mining, data matching, recording of "click trails" on the web, and so on [see Tavani, 1999].

The variety of privacy-related issues generated by computer technology has led philosophers and other thinkers to re-examine the concept of privacy itself. Since the mid-1960s, for example, a number of scholars have elaborated a theory of privacy defined as "control over personal information" (see, for example, [Westin, 1967], [Miller, 1971], [Fried, 1984] and [Elgesem, 1996]). On the other hand, philosophers Moor and Tavani have argued that control of personal information is insufficient to establish or protect privacy, and "the concept of privacy itself is best defined in terms of restricted access, not control" [Tavani and Moor, 2001] (see also [Moor, 1997]). In addition, Nissenbaum has argued that there is even a sense of privacy in public spaces, or circumstances "other than the intimate." An adequate definition of privacy, therefore, must take account of "privacy in public" [Nissenbaum, 1998]. As computer technology rapidly advances -- creating ever new possibilities for compiling, storing, accessing and analyzing information -- philosophical debates about the meaning of ‘privacy’ will likely continue (see also [Introna, 1997]).

Questions of anonymity on the internet are sometimes discussed in the same context with questions of privacy and the internet, because anonymity can provide many of the same benefits as privacy. For example, if someone is using the internet to obtain medical or psychological counseling, or to discuss sensitive topics (for example, AIDS, abortion, gay rights, venereal disease, political dissent), anonymity can afford protection similar to that of privacy. Similarly, both anonymity and privacy on the internet can be helpful in preserving human values such as security, mental health, self-fulfillment and peace of mind. Unfortunately, privacy and anonymity also can be exploited to facilitate unwanted and undesirable computer-aided activities in cyberspace, such as money laundering, drug trading, terrorism, or preying upon the vulnerable (see [Marx, 2001] and [Nissenbaum, 1999]).

3.4 Intellectual Property

One of the more controversial areas of computer ethics concerns the intellectual property rights connected with software ownership. Some people, like Richard Stallman who started the Free Software Foundation, believe that software ownership should not be allowed at all. He claims that all information should be free, and all programs should be available for copying, studying and modifying by anyone who wishes to do so [Stallman, 1993]. Others argue that software companies or programmers would not

invest weeks and months of work and significant funds in the development of software if they could not get the investment back in the form of license fees or sales [Johnson, 1992]. Today's software industry is a multibillion dollar part of the economy; and software companies claim to lose billions of dollars per year through illegal copying ("software piracy"). Many people think that software should be ownable, but "casual copying" of personally owned programs for one's friends should also be permitted (see [Nissenbaum, 1995]). The software industry claims that millions of dollars in sales are lost because of such copying. Ownership is a complex matter, since there are several different aspects of software that can be owned and three different types of ownership: copyrights, trade secrets, and patents. One can own the following aspects of a program:

1. The "source code" which is written by the programmer(s) in a high-level computer language like Java or C++.
2. The "object code", which is a machine-language translation of the source code.
3. The "algorithm", which is the sequence of machine commands that the source code and object code represent.
4. The "look and feel" of a program, which is the way the program appears on the screen and interfaces with users.

A very controversial issue today is owning a patent on a computer algorithm. A patent provides an exclusive monopoly on the use of the patented item, so the owner of an algorithm can deny others use of the mathematical formulas that are part of the algorithm. Mathematicians and scientists are outraged, claiming that algorithm patents effectively remove parts of mathematics from the public domain, and thereby threaten to cripple science. In addition, running a preliminary "patent search" to make sure that your "new" program does not violate anyone's software patent is a costly and time-consuming process. As a result, only very large companies with big budgets can afford to run such a search. This effectively eliminates many small software companies, stifling competition and decreasing the variety of programs available to the society [The League for Programming Freedom, 1992].

3.5 Professional Responsibility

Computer professionals have specialized knowledge and often have positions with authority and respect in the community. For this reason, they are able to have a significant impact upon the world, including many of the things that people value. Along with such power to change the world comes the duty to exercise that power responsibly [Gotterbarn, 2001]. Computer professionals find themselves in a variety of professional relationships with other people [Johnson, 1994], including:

employer	-- employee
client	-- professional
professional	-- professional
society	-- professional

These relationships involve a diversity of interests, and sometimes these interests can come into conflict with each other. Responsible computer professionals, therefore, will be aware of possible conflicts of interest and try to avoid them.

Professional organizations in the USA, like the Association for Computing Machinery (ACM) and the Institute of Electrical and Electronic Engineers (IEEE), have established codes of ethics, curriculum guidelines and accreditation requirements to help computer professionals understand and manage ethical responsibilities. For example, in 1991 a Joint Curriculum Task Force of the ACM and IEEE adopted a set of guidelines ("Curriculum 1991") for college programs in computer science. The guidelines say that a significant component of computer ethics (in the broad sense) should be included in undergraduate education in computer science [Turner, 1991].

In addition, both the ACM and IEEE have adopted Codes of Ethics for their members. The most recent ACM Code (1992), for example, includes "general moral imperatives", such as "avoid harm to others" and "be honest and trustworthy". And also included are "more specific professional responsibilities" like "acquire and maintain professional competence" and "know and respect existing laws pertaining to professional work." The IEEE Code of Ethics (1990) includes such principles as "avoid real or perceived conflicts of interest whenever possible" and "be honest and realistic in stating claims or estimates based on available data."

The Accreditation Board for Engineering Technologies (ABET) has long required an ethics component in the computer engineering curriculum. And in 1991, the Computer Sciences Accreditation Commission/Computer Sciences Accreditation Board (CSAC/CSAB) also adopted the requirement that a significant component of computer ethics be included in any computer sciences degree granting program that is nationally accredited [Conry, 1992].

It is clear that professional organizations in computer science recognize and insist upon standards of professional responsibility for their members.

3.6 Globalization

Computer ethics today is rapidly evolving into a broader and even more important field, which might reasonably be called "global information ethics". Global networks like the Internet and especially the world-wide-web are connecting people all over the earth. As Krystyna Gorniak-Kocikowska perceptively notes in her paper, "The Computer Revolution and the Problem of Global Ethics" [Gorniak-Kocikowska, 1996], for the first time in history, efforts to develop mutually agreed standards of conduct, and efforts to advance and defend human values, are being made in a truly global context. So, for the first time in the history of the earth, ethics and values will be debated and transformed in a context that is not limited to a particular geographic region, or constrained by a specific religion or culture. This may very well be one of the most important social developments in history. Consider just a few of the global issues:

Global Laws

If computer users in the United States, for example, wish to protect their freedom of speech on the internet, whose laws apply? Nearly two hundred countries are already interconnected by the internet, so the United States Constitution (with its First Amendment protection for freedom of speech) is just a "local law" on the internet -- it does not apply to the rest of the world. How can issues like freedom of speech, control of "pornography", protection of intellectual property, invasions of privacy, and many others to be governed by law when so many countries are involved? If a citizen in a European country, for example, has internet dealings with someone in a far-away land, and the government of that land considers those dealings to be illegal, can the European be tried by the courts in the far-away country?

Global Cyberbusiness

The world is very close to having technology that can provide electronic privacy and security on the internet sufficient to safely conduct international business transactions. Once this technology is in place, there will be a rapid expansion of global "cyberbusiness". Nations with a technological infrastructure already in place will enjoy rapid economic growth, while the rest of the world lags behind. What will be the political and economic fallout from rapid growth of global cyberbusiness? Will accepted business practices in one part of the world be perceived as "cheating" or "fraud" in other parts of the world? Will a few wealthy nations widen the already big gap between rich and poor? Will political and even military confrontations emerge?

Global Education

If inexpensive access to the global information net is provided to rich and poor alike -- to poverty-stricken people in ghettos, to poor nations in the "third world", etc.-- for the first time in history, nearly everyone on earth will have access to daily news from a free press; to texts, documents and art works from great libraries and museums of the world; to political, religious and social practices of peoples everywhere. What will be the impact of this sudden and profound "global education" upon political dictatorships, isolated communities, coherent cultures, religious practices, etc.? As great universities of the world begin to offer degrees and knowledge modules via the internet, will "lesser" universities be damaged or even forced out of business?

Information Rich and Information Poor

The gap between rich and poor nations, and even between rich and poor citizens in industrialized countries, is already disturbingly wide. As educational opportunities, business and employment opportunities, medical services and many other necessities of life move more and more into cyberspace, will gaps between the rich and the poor become even worse?

3.7 The Metaethics of Computer Ethics

Given the explosive growth of Computer ethics during the past two decades, the field appears to have a

very robust and significant future. Two important thinkers, however, Krystyna Gorniak-Kocikowska and Deborah Johnson, have recently argued that computer ethics will disappear as a separate branch of ethics. In 1996 Gorniak-Kocikowska predicted that computer ethics, which is currently considered a branch of applied ethics, will eventually evolve into something much more.[1] According to her hypothesis, "local" ethical theories like Europe's Benthamite and Kantian systems and the ethical systems of other cultures in Asia, Africa, the Pacific Islands, etc., will eventually be superceded by a global ethics evolving from today's computer ethics. "Computer" ethics, then, will become the "ordinary" ethics of the information age.

In her 1999 ETHICOMP paper [Johnson, 1999], Johnson expressed a view which, upon first sight, may seem to be the same as Gorniak's.[2] A closer look at the Johnson hypothesis reveals that it is a different kind of claim than Gorniak's, though not inconsistent with it. Johnson's hypothesis addresses the question of whether or not the name "computer ethics" (or perhaps "information ethics") will continue to be used by ethicists and others to refer to ethical questions and problems generated by information technology. On Johnson's view, as information technology becomes very commonplace -- as it gets integrated and absorbed into our everyday surroundings and is perceived simply as an aspect of ordinary life -- we may no longer notice its presence. At that point, we would no longer need a term like "computer ethics" to single out a subset of ethical issues arising from the use of information technology. Computer technology would be absorbed into the fabric of life, and computer ethics would thus be effectively absorbed into ordinary ethics.

Taken together, the Gorniak and Johnson hypotheses look to a future in which what we call "computer ethics" today is globally important and a vital aspect of everyday life, but the name "computer ethics" may no longer be used.

Stanford Encyclopedia of Philosophy
Notes to Computer Ethics

Notes

1. It will evolve, she said, into a system of global ethics applicable in every culture on earth. In Gorniak-Kocikowska [1996], we find:

> Just as the major ethical theories of Bentham and Kant were developed in response to the printing press revolution, so a new ethical theory is likely to emerge from computer ethics in response to the computer revolution. The newly emerging field of information ethics, therefore, is much more important than even its founders and advocates believe. (p. 177)
>
> ... The very nature of the Computer Revolution indicates that the ethic of the future will have a global character. It will be global in a spatial sense, since it will encompass the entire Globe. It will also be global in the sense that it will address the totality of human actions and relations. (p. 179)
>
> ... the rules of computer ethics, no matter how well thought through, will be ineffective unless respected by the vast majority of or maybe even all computer users. This means that in the future, the rules of computer ethics should be respected by the majority (or all) of the human inhabitants of the Earth ... . In other words, computer ethics will become universal, it will be a global ethic. (p. 187)

2. In Johnson [1999], we find:

> I offer you a picture of computer ethics in which computer ethics as such disappears. ... We will be able to say both that computer ethics has become ordinary ethics and that ordinary ethics has become computer ethics. (pp. 17-18)

Medieval Theories of Causality

Causality plays an important role in medieval philosophical writing: the dominant genre of medieval academic writing was the commentary on an authoritative work, very often a work of Aristotle. Of the works of Aristotle thus commented on, the *Physics* plays a central role. Other of Aristotle's scientific works -- *On the Heavens and the Earth*, *On Generation and Corruption* - are also significant: so there is a rather daunting body of work to survey.

One might, though, be tempted to argue that this concentration on causality is simply an effect of reading Aristotle, but this would be too hasty. Medieval thinkers were attracted to the problem of causality long before most of Aristotle's texts became available in the thirteenth century: already in the twelfth century the created universe was seen as a rational manifestation of God (Wetherbee 1988, p. 25), and, consequently, the rational investigation of the universe was seen as a way of approaching God: "In the creation of things", says William of Conches, "divine power, wisdom and goodness are beheld" (William of Conches, *Glosa super Platonem*, p. 60).

Even apart from direct literary influence, the nature of the philosophical and theological themes which were popular in the Middle Ages also led to an emphasis on causality. Writers studied the interrelationship of divine grace and natural processes, the role of the will in ethics, free will and determinism: all of these problems have an important causal component. These questions were often handled by methods which might seem to us to be extraordinarily naturalistic - naturalistic, of course, in the sense of the modes of natural investigation which were current at the time. It comes as no surprise to know that many medieval thinkers discussed the question of whether divine grace can increase: what *is* surprising is that many of the discussions use the technical tools of Aristotle's physical and biological works, tools which were originally developed to discuss problems of continuity and change in the natural world. What is even more surprising is the technical proficiency of many of these discussions: fourteenth-century work on this topic gave rise to very acute analyses of the variation of continuous quantities (see Murdoch 1975).

What should become evident during this survey is the extremely tight and complex interconnection between medieval causal theories and medieval ontology. After Aristotle's texts had been assimilated, almost all medieval academic theories had an ontology which was basically hylomorphic: substances were composites of matter and form, and change was described as the loss of one form and the acquisition of another. Form was not merely shape, but an active principle: the form of a thing was responsible for its causal role (White 1984). Furthermore, in any causal interaction, the allocation of active and passive roles to the individuals involved tended to be thought of as unproblematic. Although many aspects of

Aristotle's causal theories were extensively and critically debated, this basic hylomorphism persisted throughout; and it is this, rather than anything more arcane, which often poses the greatest problems in assimilating, or evaluating, medieval thought on these topics.

Causality and Motion

The term ‘motion’, in Aristotelean philosophy, can stand for a wide range of changes of state, and not simply changes of place (the latter is usually known as *local* motion). Aristotle's *Physics* is basically an exhaustive study of motion in this very wide sense. However, local motion is an interesting topic, and we shall start with it.

Motions are, in Aristotle's physics, classified into *natural* and *violent*. A paradigmatic example of natural (local) motion is the motion of a freely falling body, whereas an example of violent (local) motion would be the motion of a thrown body. If we throw a body, then it is relatively unproblematic to account for the motion when it is in contact with our hand: what is difficult is to account for its continued motion thereafter. Aristotle's theory accounts for it by saying that, when it is moving, a temporary vacuum is caused behind it, and, in order to fill in this vacuum, air rushes around from the front, thus leaving a void in front of the projectile which is filled by the continued motion of the projectile. This explanation was vulnerable to a large number of objections -- for example, it is clearly easier to throw a moderately heavy object, such as a stone, than a light object, such as a bean, whereas light objects ought to be more susceptible than others to motions of the air. And Aristotle's theory, when confronted with the example of two stones thrown in opposite directions so as to pass near to one another, cannot consistently say how the air is supposed to move in the neighbourhood of their close encounter. These objections were made by numerous medieval authors, most significantly by John Buridan (*De Caelo et Mundo* III, qu. 22, pp. 227ff.) and Nicole Oresme (*Du ciel et du monde* II, ch. 25ff., pp. 525ff.).

This critique of Aristotle's theory of projectile motion did not come out of nowhere. Aristotle relied on a concept of natural motion, and *that*, in turn, relied on a concept of natural place: natural motion was motion towards the natural place of a body (i.e. motion downwards in the case of earth, and motion upwards in the case of fire). (Aristotle, *Physics* IV.5, 212b30-213a5) Ockham is already quite equivocal

about the concept of natural place: and this is for several reasons.

1. One is that -- as we shall see later -- he is generally quite suspicious about teleology, and the concept of natural place is basically a teleological one. Correspondingly, Ockham attempts -- not very successfully -- to explain the kinematics associated with natural place in terms of *efficient* causality. (Ockham, *Expositio Physicorum* IV, c6: *Opera Philosophica* V, p. 78; Goddu 1984, pp. 122ff.).
2. Another reason is because of several examples which tend to undermine the difference between rest and motion. Ockham, and many other medievals, have reductionist accounts of place in terms of contact between bodies; the place of a body is just the surfaces of the bodies surrounding it (Ockham, *Expositio Physicorum* IV, c6: *Opera Philosophica* V, pp. 55ff.). So, if we have a ship in a river, which is flowing, is the place of the ship the surface of the surrounding water? Is this, then, a moving place? And what, then, would be the relation between that moving place and fixed places? Ockham eventually decides that there are only fixed places, but his arguments are not very strong, and one is left with the impression that the very ideas of rest and motion have become somewhat problematic. (Ockham, *Expositio Physicorum* IV, c7: *Opera Philosophica* V, pp. 79ff.)
3. The final reason is motivated by a theological example: we can suppose that God could create another world than this, but, in that case, what would the earth of that world do? Would it move towards the centre of *this* world (which seems to us to be the natural place of earth)? Or towards the centre of the other world? (Ockham, I *Sent.*, d. 44: *Opera Theologica* IV, pp. 655-56; Goddu 1984, p. 124. See also Marsilius of Inghen, *Si essent plures mundi*.)

Correspondingly, both Buridan and Oresme are sceptical, not only about Aristotle's theory of projectile motion, but also about the related notions of natural place, motion, and rest. They both state -- Oresme far more emphatically -- that it would be consistent with all we observe if the earth were to rotate while the heavens remained at rest; Oresme and Buridan have, on these grounds, been described as "precursors of Galileo".

However, what is more interesting for us are the alternative causal accounts that Buridan and Oresme adopted: they both said that projectiles move violently because of a form inherent in them, which led them to move in a non-natural direction, and which naturally decayed. This form was known as ‘impetus’, and was a common theme in the philosophy of the thirteenth and fourteenth centuries; some version of an impetus theory goes back to the early thirteenth century (Wood 1992). There was, especially in the fourteenth century, a considerable amount of quantitative work on impetus which attempted to establish such things as the law according to which impetus decayed (Weisheipl 1982, pp. 535ff.).

What is significant here is that -- despite the radical changes in cosmology -- this is is still an extremely *medieval* theory: causation is due to forms inhering in substances, and there is a division of the substances involved into agents and patients. Instead of there being a single form involved in projectile motion -- the form of heaviness, responsible for natural motion downwards -- there are two, weight and impetus, and the two conflict. The basic ontology is still the same, and the division into agents and patients, though its details may have changed, still persists. Furthermore, despite persistent doubts, there is still something of a distinction between motion and rest, and motion can only be the result of agency. Contrast this with

Galileo's or -- still more -- Newton's account: here uniform motion and rest are treated on an equal footing, and, consequently, there can be no unequivocal distinction between motion and rest. So, although Buridan and Galileo are -- in some sense -- precursors of Galileo, their causal ontology is still, in important respects, thoroughly medieval (Maier 1964)

Causality, Self-Motion, and the Will

An example of motion in the wider sense is an act of the will: it is a change of state of some entity (namely the mind or soul), but would not have been thought of as *local* motion by most medieval thinkers -- thought and will were generally regarded as immaterial processes (see Cross 1999, p. 75).

Aristotle has a picture of willed action in which actions are caused by combinations of beliefs and desires: these belief-desire states are not, of course, themselves actions (Normore 1998). This picture of the will fits with one of Aristotle's major causal doctrines: that nothing causes a change in itself.

However, Aristotle's picture of the will was not undisputed in the Middle Ages: as early as the twelfth century, Anselm had outlined a theory in which the will was a self-mover, and in which moral conflict was explained by the presence of two wills in the same person (Normore 1998, p. 28). This position was later taken up, in conscious opposition to Aristotle, by thinkers in the Franciscan school -- Peter Olivi, and then Scotus and Ockham.

Scotus follows a modified Anselmian line, speaking of a single will, with two inclinations: one towards self-fulfillment, the other towards justice). It is the presence of these two inclinations which distinguishes willed causes from natural causes: natural causes are determined to perform their acts (unless impeded), whereas the will is not thus determined (Scotus, *Metaphysics* IV, 9: in Scotus, *On the Will and Morality*, pp. 136ff.; Lee 1998; Cross 1999, pp. 84ff.). The will is thus self-determining, rather than determined by its end, and so Scotus affirms self-motion in psychology. In fact, he goes further, and admits self-motion in physical cases as well: for example, a falling object is actively moving towards its goal, and its motion is caused by itself (because it is heavy); so this, too, is an instance of self-motion (Effler 1962).

Ockham expands on Scotus's theory of the will to deny that actions are properly explained by their ends: we are *influenced* by ends, but our actions are not *necessitated* by them and thus not caused by them (Ockham, *Quodlibet* I, qu. 16: *Opera Theologica* IX, pp. 87ff.). A free agent is one which, under exactly the same circumstances, could have chosen otherwise; and so a free agent can reject the Beatific Vision (and, in fact, actively turn to any other object whatever). (Ockham, *Quodlibet* IV, q. 1: *Opera Theologica* IX, pp. 292ff.).

Causal Accounts of Perception

Perception was, throughout the Middle Ages, a contentious topic, and it was also a topic in which the answers to strictly *causal* questions could influence philosophical positions in other areas (for example,

on whether certain knowledge of external entities was attainable). The "traditional" view, dating back to Roger Bacon in the mid-thirteenth century, was that physical objects were known because they caused a succession of likenesses, or *species*, first in the medium between the object and the perceiver, then in the senses, and finally in the intellect, of the perceiver (Tachau 1988, pp. 3ff.). This position was attacked by thinkers such as Henry of Ghent, Peter Olivi, and Duns Scotus. Interestingly, many of these criticisms tend towards a relational account of perception, in which -- although *species* still play a role -- the role that they play is to be a means by which we know things, and in which the *species* themselves are not known directly but only by reflection. (Tachau 1988, p. 66)

Ockham then radicalised these critiques by denying that there are any such *species* at all: perception and other phenomena which were usually explained by *species* -- the sun heating or illuminating physical objects, for example -- were now explained by action at a distance (Tachau 1988, pp. 130ff.). There was a similar debate about the causal mechanisms behind memory, where, again, Ockham denied a *species*-based account; however, in the case of memory, he replaced species not with action at a distance but with habits (Wolter and Adams 1993).

Ockham denies species not on the basis of empirical evidence, or on the basis of epistemological arguments, but purely and simply on the basis of his razor: if we deny *species*, then we can give an account of the phenomena which uses fewer entities, because *species* are entities. Although this position of Ockham's did not have much influence on his contemporaries or followers -- it is, after all, extremely implausible -- it is a good example of how causal reasoning is affected by tacit ontological assumptions: the fact that *species* were seen as entities and the fact that Ockham had a programme of reducing the number of entities, led to an account of perception which tried to do away with *species*. On the other hand, action at a distance was, despite its implausibility, entirely unaffected by Ockham's critique. And, similarly, Ockham's account was not noticeably *simpler* than the accounts it criticised, which shows how far Ockham's own razor was from the principles of simplicity and the like, which are usually considered to be its modern equivalents.

Causality, Knowledge and Necessity

There is a persistent supposition -- see, for example, (Gilson 1937) - that Ockham, and many of his fourteenth-century followers, had a basically Humean position on causality; this supposition has deep historical roots (Nadler 1996), but is inaccurate (Adams 1987, pp. 741ff.).

The supposedly Humean position has three basic assertions: that there is nothing more to causality than the regular sequence of phenomena, that such a regular sequence cannot give a necessary connection, and that, consequently, we can have no certain knowledge of causal relations.

One item in this chain of argument has some textual support in Ockham: he did not believe that the relation of efficient causality was a *thing* distinct from its *relata* (Ockham, *Quodlibet* VI, qu. 12: *Opera Theologica* IX, pp. 629ff.) However, one can still believe this and hold that causality is a real relation, and Ockham *did* so believe (Adams 1987, p. 744; White 1990b). So this link in the chain is not found in

Ockham.

The "Humean" argument, in addition, makes a detour through psychology: as Adams analyses it, it relies on a premise like "There can be nothing more in concepts than there actually is in intuitions" (Adams 1987, p. 744). But such a detour through psychology, though widely practiced in the eighteenth century, was somewhat foreign to medieval thought (White 1990a).

Even though pseudo-Humean arguments of this sort cannot reasonably be ascribed to Ockham or to most other medieval thinkers -- with the possible exception of Nicholas of Autrecourt -- there still remains the question of what their views on these questions actually were. Since the medievals generally did not conflate ontological and epistemological issues, there are two questions: first about the necessity of causality, and second about whether we can know causal propositions with certainty.

Causality and Necessity

Medieval thinkers believed that the world was created by God, and so a question like "Is proposition P contingent?" were seen as equivalent to the question "Could God have created a world in which P does not hold?". So our question can be reduced to one about divine power.

A very common theme in medieval thought is the distinction between God's absolute and ordered, or ordained, power (*potentia absoluta* and *potentia ordinata*). This distinction goes back to early medieval thought (Moonan 1994), and was extensively used in later medieval philosophy (Courtenay 1971; Adams 1987, pp. 1186ff.).

God's absolute power is unrestricted power. According to this power, God can create a huge variety of possible worlds. One frequently used principle is this: given two distinct entities, God can create a world in which one of them, but not the other, exists, or, in *this* world, God can destroy one of them, leaving the other intact. We should note that this is not exactly innocuous; ontologically, it amounts to some sort of logical atomism. See (White 1990b).

But God will, in practice, not exercise absolute power: as Aquinas puts it, "what is attributed to the divine power insofar as the command of a just will executes it, God is said to be able to do with respect to His ordered power". (Aquinas, *Summa theologiae* I, qu. 25, a. 5, ad 1) So there are limits to God's ordained power (which come from the concept of a just agent): inside the space of worlds which God could create by absolute power, there is a space of worlds which could be created by ordered power. It is this smaller space of worlds which is relevant for our question of the necessity of causal connections. And, with respect to God's ordered power, there was a wide range of causal assertions which were regarded as necessary by medieval thinkers.

Knowing Causal Propositions: Demonstration

As far as our knowledge of causal propositions is concerned, we can again draw a distinction. One

question is this: do medieval thinkers, in practice, establish causal propositions on the basis of argument? And the other is this: what sort of metatheory of causal argument do the medievals have?

The answer to the first question is quite straightforward. Ockham, like other fourteenth-century theologians, frequently gives instances where we can make reliable causal inferences and come to know causal propositions on the basis of experience (Ockham, *Ordinatio* Prologue, qu. 2: *Opera Theologica* I, p. 87) These arguments frequently rely on a theory of natural kinds: for example, Ockham writes

> Because someone sees that, after eating such an herb, health follows for someone with a fever, and because he can eliminate all other causes of health for that person, he knows evidently that that herb was the cause of health; and thus he has knowledge (*experimentum*) in the singular case. It is, however, obvious to him that all individuals of the same kind have an effect of the same kind in a patient of the same kind; and thus he assents evidently, as to a principle, that every herb of such a kind cures fever. (Ockham, *Ordinatio* prologue, qu. 2: *Opera Theologica* I, p. 87)

The second question is that of a metatheory. Here the story becomes somewhat more complicated. There was a generally accepted metatheory, namely that of Aristotle's *Posterior Analytics*, according to which scientific demonstrations were syllogistic proofs, based on necessary and self-evident premises. There were two sorts of these: proofs of the simple fact (*demonstrationes quia*) and proofs of the reasoned fact (*demonstrationes propter quid*). In the latter, the syllogisms involved must have middle terms that are *causes* of the state of affairs which is to be demonstrated. This gives a theory of scientific reasoning in which the structure of the arguments is intimately tied up with the structure of the causal chains that they demonstrate.

There is, indeed, an extensive literature of medieval commentaries on the *Posterior Analytics*, and much of this literature is very important; we find in it a great deal of material on the authors' attitudes to necessity, the structure of science, the relation between various sciences, the autonomy of philosophy *vis-à-vis* theology, and the like. However, it cannot be taken to be automatically relevant to the *practice* of reasoning in the Middle Ages: the logical metatheory (that of the syllogism) is far too restrictive, and the conditions placed on scientific demonstrations are far too stringent, for it to be a plausible description of very many actual processes of reasoning, in the Middle Ages or at any other time.

Final Causes

We often find in Aristotle and in the literature influenced by him an enumeration of four types of cause: formal, material, efficient and final. The first two are uses of ‘cause’ in a somewhat wider sense than is current nowadays: the term here simply means ‘explanation in general’ (Ockham, *Expositio Physicorum* II, c11: *Opera Philosophica* IV, p. 348), and explanations by means of matter and form were common both in Aristotle and in the literature. Efficient causes are what we would now simply call ‘causes’. Final causes, however, are problematic: a final cause is an end or a purpose, and, whereas it is clear that *rational* agents act for the sake of ends, it is not clear that much else does. Furthermore, it also seems

clear to us that the causality of a rationally pursued goal can be reduced to efficient causality.

Aristotle, however, has a much stronger position on final causality: he believes that there are processes in nature (the growing of a tree, for example) which are completed and regulated by a final state, or end, towards which they tend. As Adams puts it,

> According to Aristotelian metaphysics, natures are complexes of powers. When appropriately coordinated, the collective exercise of such powers converges on an end. In the sublunary world, elemental powers are simple and deterministic. Even where more complex living things are concerned, the "coordination" of their powers is "built-in" in such a fashion that -- given relevant circumstances -- they function to achieve their end. (Adams 1996, p. 499)

Aristotle's natural science tends to be governed by the biological paradigm, and it is clear that, for him, final causes in this strong sense are extremely pervasive. He also argues in the *Physics* that natural processes cannot all be explained by final causality alone, which implies that final causality cannot, in general, be reduced to efficient causality.

The medieval literature is far from unanimous on these questions. William of Ockham, for example, who wrote several commentaries on Aristotle's *Physics*, and who discusses these questions at numerous places in his commentary on Aristotle's *Physics*, hardly has a uniform position. He is quite happy with explanations of natural phenomena by means of efficient causes in general, but he will also often speak of final causes: what is unclear is whether the final causes he speaks of (with varying degrees of strength in different works) have any explanatory role to play that cannot be reduced to efficient causality (Adams 1998).

Conditionals

Take a sentence in the indicative mood, suitable for making a statement: "We'll be home by ten", "Tom cooked the dinner". Attach a conditional clause to it, and you have a sentence which makes a conditional statement: "We'll be home by ten if the train is on time", "If Mary didn't cook the dinner, Tom cooked it". A conditional sentence "If *A*, *C*" or "*C* if *A*" thus has two contained sentences or sentence-like clauses. *A* is called the antecedent, *C* the consequent. If you understand *A* and *C*, and you have mastered the conditional construction (as we all do at an early age), you understand "If *A*, *C*". What does "if" mean? Consulting the dictionary yields "on condition that; provided that; supposing that". These are adequate synonyms. But we want more than synonyms. A theory of conditionals aims to give an account of the conditional construction which explains when conditional judgements are acceptable, which inferences involving conditionals are good inferences, and why this linguistic construction is so important. Despite intensive work of great ingenuity, this remains a highly controversial subject.

1. Introduction

First let us delimit our field. The examples with which we began are traditionally called "indicative conditionals". There are also "subjunctive" or "counterfactual" conditionals like "Tom would have cooked the dinner if Mary had not done so", "We would have been home by ten if the train had been on time". Counterfactuals are the subject of a separate entry, and theories addressing them will not be discussed here. That there is some difference between indicatives and counterfactuals is shown by pairs of examples like "If Oswald didn't kill Kennedy, someone else did" and "If Oswald hadn't killed Kennedy, someone else would have": you can accept the first yet reject the second (Adams (1970)). That

there is not a huge difference between them is shown by examples like the following: "Don't go in there", I say, "If you go in you will get hurt". You look sceptical but stay outside, when there is large crash as the roof collapses. "You see", I say, "if you had gone in you would have got hurt. I told you so."

It is controversial how best to classify conditionals. According to some theorists, the forward-looking "indicatives" (those with a "will" in the main clause) belong with the "subjunctives" (those with a "would" in the main clause), and not with the other "indicatives". (See Gibbard (1981, pp. 222-6), Dudman (1984, 1988), Bennett (1988). Bennett (1995) changed his mind. Jackson (1990) defends the traditional view.) The easy transition from typical "wills" to "woulds" is indeed a datum to be explained. Still, straightforward statements about the past, present or future, to which a conditional clause is attached -- the traditional class of indicative conditionals -- do (in my view) constitute a single semantic kind. The theories to be discussed do not fare better or worse when restricted to a particular subspecies.

As well as conditional statements, there are conditional commands, promises, offers, questions, etc.. As well as conditional beliefs, there are conditional desires, hopes, fears, etc.. Our focus will be on conditional statements and what they express -- conditional beliefs; but we will consider which of the theories we have examined extends most naturally to these other kinds of conditional.

Three kinds of theory will be discussed. In §2 we compare truth-functional and non-truth-functional accounts of the truth conditions of conditionals. In §3 we examine what I call the suppositional theory: that conditional judgements essentially involve suppositions. On development, it turns out to be incompatible with construing conditionals as statements with truth conditions. §4 looks at some responses from advocates of truth conditions. In §5 we consider a wider variety of conditional speech acts and propositional attitudes.

Where I need to distinguish between different interpretations, I write "$A \supset B$" for the truth-functional conditional, "$A \rightarrow B$" for a non-truth-functional conditional and "$A \Rightarrow B$" for the conditional as interpreted by the suppositional theory; and for brevity I call protagonists of the three theories Hook, Arrow and Supp, respectively. I use "~" for negation.

2. Truth Conditions for Indicative Conditionals

2.1 Two Kinds of Truth Condition

The generally most fruitful, and time-honoured, approach to specifying the meaning of a complex sentence in terms of the meanings of its parts, is to specify the truth conditions of the complex sentence, in terms of the truth conditions of its parts. A semantics of this kind yields an account of the validity of arguments involving the complex sentence, given the conception of validity as necessary preservation of truth. Throughout this section we assume that this approach to conditionals is correct. Let *A* and *B* be two sentences such as "Ann is in Paris" and "Bob is in Paris". Our question will be: are the truth conditions of "If *A*, *B*" of the simple, extensional, truth-functional kind, like those of "*A* and *B*", "*A* or *B*" and "It is not

the case that *A*"? That is, do the truth values of *A* and of *B* determine the truth value of "If *A*, *B*"? Or are they non-truth-functional, like those of "*A* because *B*", "*A* before *B*", "It is possible that *A*"? That is, are they such that the truth values of *A* and *B* may, in some cases, leave open the truth value of "If *A*, *B*"?

The truth-functional theory of the conditional was integral to Frege's new logic (1879). It was taken up enthusiastically by Russell (who called it "material implication"), Wittgenstein in the *Tractatus*, and the logical positivists, and it is now found in every logic text. It is the first theory of conditionals which students encounter. Typically, it does not strike students as *obviously* correct. It is logic's first surprise. Yet, as the textbooks testify, it does a creditable job in many circumstances. And it has many defenders. It is a strikingly simple theory: "If *A*, *B*" is false when *A* is true and *B* is false. In all other cases, "If *A*, *B*" is true. It is thus equivalent to "~(*A*&~*B*)" and to "~*A* or *B*". "$A \supset B$" has, by stipulation, these truth conditions.

If "if" is truth-functional, this is the right truth function to assign to it: of the sixteen possible truth-functions of *A* and *B*, it is the only serious candidate. First, it is uncontroversial that when *A* is true and *B* is false, "If *A*, *B*" is false. A basic rule of inference is modus ponens: from "If *A*, *B*" and *A*, we can infer *B*. If it were possible to have *A* true, *B* false and "If *A*, *B*" true, this inference would be invalid. Second, it is uncontroversial that "If *A*, *B*" is *sometimes* true when *A* and *B* are respectively (true, true), or (false, true), or (false, false). "If it's a square, it has four sides", said of an unseen geometric figure, is true, whether the figure is a square, a rectangle or a triangle. Assuming truth-functionality -- that the truth value of the conditional is *determined* by the truth values of its parts -- it follows that a conditional is *always* true when its components have these combinations of truth values.

Non-truth-functional accounts agree that "If *A*, *B*" is false when *A* is true and *B* is false; and they agree that the conditional is sometimes true for the other three combinations of truth-values for the components; but they deny that the conditional is always true in each of these three cases. Some agree with the truth-functionalist that when *A* and *B* are both true, "If *A*, *B*" must be true. Some do not, demanding a further relation between the facts that *A* and that *B* (see Read (1995)). This dispute need not concern us, as the arguments which follow depend only on the feature on which non-truth-functionalists agree: that when *A* is false, "If *A*, *B*" may be either true or false. For instance, I say (*) "If you touch that wire, you will get an electric shock". You don't touch it. Was my remark true or false? According to the non-truth-functionalist, it depends on whether the wire is live or dead, on whether you are insulated, and so forth. Robert Stalnaker's (1968) account is of this type: consider a possible situation in which you touch the wire, and which otherwise differs minimally from the actual situation. (*) is true (false) according to whether or not you get a shock in that possible situation.

Let *A* and *B* be two logically independent propositions. The four lines below represent the four incompatible logical possibilities for the truth values of *A* and *B*. "If *A*, *B*", "If ~*A*, *B*" and "If *A*, ~*B*" are interpreted truth-functionally in columns (i)-(iii), and non-truth-functionally (when their antecedents are false) in columns (iv)-(vi). The non-truth-functional interpretation we write "$A \rightarrow B$". "T/F" means both truth values are possible for the corresponding assignment of truth values to *A* and *B*. For instance, line 4, column (iv), represents two possibilities for *A*, *B*, If *A*, *B*, (F, F, T) and (F, F, F).

Truth-Functional Interpretation

			(i)	(ii)	(iii)
	A	*B*	$A \supset B$	$\sim A \supset B$	$A \supset \sim B$
1.	T	T	T	T	F

4.	F	F	T/F	F	T/F

2.2 Arguments for Truth-Functionality

The main argument points to the fact that minimal knowledge that the truth-functional truth condition is satisfied is enough for knowledge that if *A*, *B*. Suppose there are two balls in a bag, labelled *x* and *y*. All you know about their colour is that at least one of them is red. That's enough to know that if *x* isn't red, *y* is red. Or: all you know is that they are not both red. That's enough to know that if *x* is red, *y* is not red.

Suppose you start off with no information about which of the four possible combinations of truth values for *A* and *B* obtains. You then acquire compelling reason to think that either *A* or *B* is true. You don't have any stronger belief about the matter. In particular, you have no firm belief as to whether *A* is true or not. You have ruled out line 4. The other possibilities remain open. Then, intuitively, you are justified in inferring that if ~*A*, *B*. Look at the possibilities for *A* and *B* on the left. You have eliminated the possibility that both *A* and *B* are false. So if *A* is false, only one possibility remains: *B* is true.

The truth-functionalist (call him Hook) gets this right. Look at column (ii). Eliminate line 4 and line 4 only, and you have eliminated the only possibility in which "$\sim A \supset B$" is false. You know enough to

conclude that "$\sim A \supset B$" is true.

The non-truth-functionalist (call her Arrow) gets this wrong. Look at column (v). Eliminate line 4 and line 4 only, and some possibility of falsity remains in other cases which have not been ruled out. By eliminating just line 4, you do not thereby eliminate these further possibilities, incompatible with line 4, in which "$\sim A \rightarrow B$" is false.

The same point can be made with negated conjunctions. You discover for sure that ~(*A*&*B*), but nothing stronger than that. In particular, you don't know whether *A*. You rule out line 1, nothing more. You may justifiably infer that if *A*, ~*B*. Hook gets this right. In column (iii), if we eliminate line 1, we are left only with cases in which "$A \supset \sim B$" is true. Arrow gets this wrong. In column (vi), eliminating line 1 leaves open the possibility that "$A \rightarrow \sim B$" is false.

The same argument renders compelling the thought that if we eliminate *just A*&~*B*, nothing stronger, i.e., we don't eliminate *A*, then we have sufficient reason to conclude that if *A*, *B*.

Here is a second argument in favour of Hook, in the style of Natural Deduction. The rule of Conditional Proof (CP) says that if *Z* follows from premises *X* and *Y*, then "If *Y*, *Z*" follows from premise *X*. Now the three premises ~(*A*&*B*), *A* and *B* entail a contradiction. So, by Reductio Ad Absurdum, from ~(*A*&*B*) and *A*, we can conclude ~*B*. So by CP, ~(*A*&*B*) entails "If *A*, ~*B*". Substitute "~*C*" for *B*, and we have a proof of "If *A*, then ~~*C*" from "~(*A*&~*C*)". And provided we also accept Double Negation Elimination, we can derive "If *A*, then *C*" from "~(*A*&~*C*)".

Conditional Proof seems sound: "From *X* and *Y*, it follows that *Z*. So from *X* it follows that if *Y*, *Z*". Yet *for no reading of "if" which is stronger than the truth-functional reading is CP valid* -- at least this is so if we treat "&" and "~" in the classical way and accept the validity of the inference: (I) ~(*A*&~*B*); *A*; therefore *B*. Suppose CP is valid for some interpretation of "If *A*, *B*". Apply CP to (I), and we get ~(*A*&~*B*); therefore if *A*, *B*, i.e., $A \supset B$ entails if *A*, *B*.

2.3 Arguments Against Truth-Functionality

The best-known objection to the truth-functional account, one of the "paradoxes of material implication", is that according to Hook, the falsity of *A* is sufficient for the truth of "If *A*, *B*". Look at the last two lines of column (i). In every possible situation in which *A* is false, "$A \supset B$" is true. Can it be right that the falsity of "She touched the wire" entails the truth of "If she touched the wire she got a shock"?

Hook might respond as follows. How do we test our intuitions about the validity of an inference? The direct way is to imagine that we know for sure that the premise is true, and to consider what we would then think about the conclusion. Now when we know for sure that ~*A*, we have no use for thoughts beginning "If *A*, ...". When you know for sure that Harry didn't do it, you don't go in for "If Harry did it ..." thoughts or remarks. In this circumstance conditionals have no role to play, and we have no practice in assessing them. The direct intuitive test is, therefore, silent on whether "If *A*, *B*" follows from ~*A*. If

our smoothest, simplest, generally satisfactory theory has the consequence that it does follow, perhaps we should learn to live with that consequence.

There may, of course, be further consequences of this feature of Hook's theory which jar with intuition. That needs investigating. But, Hook may add, even if we come to the conclusion that "$\supset$" does not match perfectly our natural-language "if", it comes close, and it has the virtues of simplicity and clarity. We have seen that rival theories also have counterintuitive consequences. Natural language is a fluid affair, and we cannot expect our theories to achieve better than approximate fit. Perhaps, in the interests of precision and clarity, in serious reasoning we should replace the elusive "if" with its neat, close relative, $\supset$.

This was no doubt Frege's attitude. Frege's primary concern was to construct a system of logic, formulated in an idealized language, which was adequate for mathematical reasoning. If "$A \supset B$" doesn't translate perfectly our natural-language "If *A*, *B*", but plays its intended role, so much the worse for natural language.

For the purpose of doing mathematics, Frege's judgement was probably correct. The main defects of $\supset$ don't show up in mathematics. There are some peculiarities, but as long as we are aware of them, they can be lived with. And arguably, the gain in simplicity and clarity more than offsets the oddities.

The oddities are harder to tolerate when we consider conditional judgements about empirical matters. The difference is this: in thinking about the empirical world, we often accept and reject propositions with degrees of confidence less than certainty. "I think, but am not sure, that *A*" plays no central role in mathematical thinking. We can, perhaps, ignore as unimportant the use of indicative conditionals in circumstances in which we are *certain* that the antecedent is false. But we cannot ignore our use of conditionals whose antecedent we think is likely to be false. We use them often, accepting some, rejecting others. "I think I won't need to get in touch, but if I do, I shall need a phone number", you say as your partner is about to go away; not "If I do I'll manage by telepathy". "I think John spoke to Mary; if he didn't he wrote to her"; not "If he didn't he shot her". Hook's theory has the unhappy consequence that *all* conditionals with unlikely antecedents are likely to be true. To think it likely that $\sim A$ is to think it likely that a sufficient condition for the truth of "$A \supset B$" obtains. Take someone who thinks that the Republicans won't win the election ($\sim R$), and who rejects the thought that if they do win, they will double income tax (*D*). According to Hook, this person has grossly inconsistent opinions. For if she thinks it's likely that $\sim R$, she must think it likely that at least one of the propositions, $\{\sim R, D\}$ is true. But that is just to think it likely that $R \supset D$. (Put the other way round, to reject $R \supset D$ is to accept $R\&\sim D$; for this is the only case in which $R \supset D$ is false. How can someone accept $R\&\sim D$ yet reject *R*?) Not only does Hook's theory fit badly the patterns of thought of competent, intelligent people. It cannot be claimed that we would be better off with $\supset$. On the contrary, we would be intellectually disabled: we would not have the power to discriminate between believable and unbelievable conditionals whose antecedent we think is likely to be false.

Arrow does not have this problem. Her theory is designed to avoid it, by allowing that "$A \rightarrow B$" may be

false when *A* is false.

The other paradox of material implication is that according to Hook all conditionals with true consequents are true: from *B* it follows that $A \supset B$. This is perhaps less obviously unacceptable: if I'm sure that *B*, and treat *A* as an epistemic possibility, I must be sure that if *A*, *B*. Again the problem becomes vivid when we consider the case when I'm only nearly sure, but not quite sure, that *B*. I think *B* *may* be false, and will be false if certain, in my view unlikely, circumstances obtain. For example, I think Sue is giving a lecture right now. I don't think that if she was seriously injured on her way to work, she is giving a lecture right now. I reject that conditional. But on Hook's account, the conditional is false only if the consequent is false. I think the consequent is true: I think a sufficient condition for the truth of the conditional obtains.

2.4 Grice's Pragmatic Defence of Truth-Functionality

H. P. Grice famously defended the truth-functional account, in his William James lectures, "Logic and Conversation", delivered in 1967 (see Grice (1989); see also Thomson (1990)). There are many ways of speaking the truth yet misleading your audience, given the standard to which you are expected to conform in conversational exchange. One way is to say something weaker than some other relevant thing you are in a position to say. Consider disjunctions. I am asked where John is. I am sure that he is in the pub, and know that he never goes near libraries. Inclined to be unhelpful but not wishing to lie, I say "He is either in the pub or in the library". My hearer naturally assumes that this is the most precise information I am in a position to give, and also concludes from the truth (let us assume) that I told him "If he's not in the pub he's in the library". The conditional, like the disjunction, according to Grice, is true if he's in the pub, but misleadingly asserted on that ground.

Another example, from David Lewis (1976, p. 143): "You won't eat those and live", I say of some wholesome and delicious mushrooms -- knowing that you will now leave them alone, deferring to my expertise. I told no lie -- for indeed you don't eat them -- but of course I misled you.

Grice drew attention, then, to situations in which a person is *justified in believing* a proposition, which would nevertheless be an unreasonable thing for the person to *say*, in normal circumstances. His lesson was salutary and important. He is right, I think, about disjunctions and negated conjunctions. Believing that John is in the pub, I can't consistently *disbelieve* "He's either in the pub or the library"; if I have any epistemic attitude to this proposition, it should be one of belief, however inappropriate for me to assert it. Similarly for "You won't eat those and live" when I know you won't eat them. But it is implausible that the difficulties with the truth-functional conditional can be explained away in terms of what is an inappropriate conversational remark. They arise at the level of belief. Thinking that John is in the pub, I may without irrationality disbelieve "If he's not in the pub he's in the library". Thinking you won't eat the mushrooms, I may without irrationality reject "If you eat them you will die". As facts about the norms to which people defer, these claims can be tested. A good enough test is to take a co-operative person, who understands that you are merely interested in her opinions about the propositions you put to her, as opposed to what would be a reasonable remark to make, and note which conditionals she assents

to. Are we really to brand as illogical someone who dissents from both "The Republicans will win" and "If the Republicans win, income tax will double"?

The Gricean phenomenon is a real one. On anyone's account of conditionals, there will be circumstances when a conditional is justifiably believed, but is liable to mislead if stated. For instance, I believe that the match will be cancelled, because all the players have 'flu. I believe that whether or not it rains, the match will be cancelled: if it rains, the match will be cancelled, and if it doesn't rain, the match will be cancelled. Someone asks me whether the match will go ahead. I say, "If it rains, the match will be cancelled". I say something I believe, but I mislead my audience -- why should I say that, when I think it will be cancelled whether or not it rains? This does not demonstrate that Hook is correct. Although I believe that the match will be cancelled, I don't believe that if all the players make a very speedy recovery, the match will be cancelled.

2.5 Compounds of Conditionals: Problems for Hook and Arrow

$\sim(A \supset B)$ is equivalent to $A\&\sim B$. Intuitively, you may safely say, of an unseen geometric figure, "It's not the case that if it's a pentagon, it has six sides". But by Hook's lights, you may well be wrong; for it may not be a pentagon, and in that case it is true that if it's a pentagon, it has six sides.

Another example, due to Gibbard (1981, pp. 235-6): of a glass that had been held a foot above the floor, you say (having left the scene) "If it broke if it was dropped, it was fragile". Intuitively this seems reasonable. But by Hook's lights, if the glass was not dropped, and was not fragile, the conditional has a true (conditional) antecedent and false consequent, and is hence false.

Grice's strategy was to explain why we don't assert certain conditionals which (by Hook's lights) we have reason to believe true. In the above two cases, the problem is reversed: there are compounds of conditionals which we confidently assert and accept which, by Hook's lights, we do not have reason to believe true.

The above examples are not a problem for Arrow. But other cases of embedded conditionals count in the opposite direction. Here are two sentence forms which are, intuitively, equivalent:

> (i) If ($A\&B$), C.
> (ii) If A, then if B, C.

(Following Vann McGee (1985) I'll call the principle that (i) and (ii) are equivalent the Import-Export Principle, or "Import-Export" for short.) Try any example: "If Mary comes then if John doesn't have to leave early we will play Bridge"; "If Mary comes and John doesn't have to leave early we will play Bridge". "If they were outside and it rained, they got wet"; "If they were outside, then if it rained, they got wet". For Hook, Import-Export holds. (Exercise: do a truth table, or construct a proof.) Gibbard (1981, pp. 234-5) has proved that for no conditional with truth conditions stronger than $\supset$ does Import-Export hold. Assume Import-Export holds for some reading of "if". The key to the proof is to consider

the formula

> (1) If ($A \supset B$) then (if A, B).

By Import-Export, (1) is equivalent to

> (2) If (($A \supset B$) & A)) then B.

The antecedent of (2) entails its consequent. So (2) is a logical truth. So by Import-Export, (1) is a logical truth. On any reading of "if", "if A, B" entails ($A \supset B$). So (1) entails

> (3) ($A \supset B$) $\supset$ (if A, B).

So (3) is a logical truth. That is, there is no possible situation in which its antecedent ($A \supset B$) is true and its consequent (if A, B) is false. That is, ($A \supset B$) entails "If A, B".

Neither kind of truth condition has proved entirely satisfactory. We still have to consider Jackson's defence of Hook, and Stalnaker's response to the problem about non-truth-functional truth conditions raised in §2.2. These are deferred to §4, because they depend on the considerations developed in §3.

3. The Suppositional Theory

3.1 Conditional Belief and Conditional Probability

Let us put truth conditions aside for a while, and ask what it is to believe, or to be more or less certain, that B if A -- that John cooked the dinner if Mary didn't, that you will recover if you have the operation, and so forth. How do you make such a judgement? You suppose (assume, hypothesise) that A, and make a hypothetical judgement about B, under the supposition that A, in the light of your other beliefs. Frank Ramsey put it like this:

> If two people are arguing "If *p*, will *q*?" and are both in doubt as to *p*, they are adding *p* hypothetically to their stock of knowledge, and arguing on that basis about *q*; ... they are fixing their degrees of belief in *q* given *p* (1929, p. 247).

A suppositional theory was advanced by J. L. Mackie (1973, chapter 4). Peter Gärdenfors's work (1986, 1988) could also come under this heading. But the most fruitful development of the idea (in my view) takes seriously the last part of the above quote from Ramsey, and emphasises the fact that conditionals can be accepted with different degrees of closeness to certainty. Ernest Adams (1965, 1966, 1975) has developed such a theory.

When we are neither certain that *B* nor certain that ~*B*, there remains a range of epistemic attitudes we may have to *B*: we may be nearly certain that *B*, think *B* more likely than not, etc.. Similarly, we may be certain, nearly certain, etc. that *B* given the supposition that *A*. Make the idealizing assumption that degrees of closeness to certainty can be quantified: 100% certain, 90% certain, etc.; and we can turn to probability theory for what Ramsey called the "logic of partial belief". There we find a well-established, indispensable concept, "the conditional probability of *B* given *A*". It is to this notion that Ramsey refers by the phrase "degrees of belief in *q* given *p*".

It is, at first sight, rather curious that the best-developed and most illuminating suppositional theory should place emphasis on uncertain conditional judgements. If we knew the truth conditions of conditionals, we would handle uncertainty about conditionals in terms of a general theory of what it is to be uncertain of the truth of a proposition. But there is no consensus about the truth conditions of conditionals. It happens that when we turn to the theory of uncertain judgements, we find a concept of conditionality in use. It is worth seeing what we can learn from it.

The notion of conditional probability entered probability theory at an early stage because it was needed to compute the probability of a conjunction. Thomas Bayes (1763) wrote:

> The probability that two ... events will both happen is ... the probability of the first [multiplied by] the probability of the second *on the supposition that* the first happens [my emphasis].

A simple example: a ball is picked at random. 70% of the balls are red (so the probability that a red ball is picked is 70%). 60% of the red balls have a black spot (so the probability that a ball with a black spot is picked, on the supposition that a red ball is picked, is 60%). The probability that a red ball with a black spot is picked is 60% of 70%, i.e. 42%.

Ramsey, arguing that "degrees of belief" should conform to probability theory, stated the same "fundamental law of partial belief":

> Degree of belief in (*p* and *q*) = degree of belief in *p* × degree of belief in *q* given *p*. (1926, p. 77)

For example, you are about 50% certain that the test will be on conditionals, and about 80% certain that you will pass, on the supposition that it is on conditionals. So you are about 40% certain that the test will be on conditionals and you will pass.

Accepting Ramsey's suggestion that "if", "given that", "on the supposition that" come to the same thing, writing "$\mathbf{p}(B)$" for "degree of belief in *B*", and "$\mathbf{p}_A(B)$" for "degree of belief in *B* given *A*", and rearranging the basic law, we have:

> $\mathbf{p}(B \text{ if } A) = \mathbf{p}_A(B) = \mathbf{p}(A\&B)/\mathbf{p}(A)$, provided $\mathbf{p}(A)$ is not 0.

Call a set of mutually exclusive and jointly exhaustive propositions a partition. The lines of a truth table constitute a partition. One’s degrees of belief in the members of a partition, idealized as precise, should sum to 100%. That is all there is to the claim that degrees of belief should have the structure of probabilities. Consider a partition of the form {*A*&*B*, *A*&~*B*, ~*A*}. Suppose someone X thinks it 50% likely that ~*A* (hence 50% likely that *A*), 40% likely that *A*&*B*, and 10% likely that *A*&~*B*. Think of this distribution as displayed geometrically, as follows. Draw a long narrow horizontal rectangle. Divide it in half by a vertical line. Write "~*A*" in the right-hand half. Divide the left-hand half with another vertical line, in the ratio 4:1, with the larger part on the left. Write "*A*&*B*" and "*A*&~*B*" in the larger and smaller cells respectively.

A&*B*	*A*&~*B*	~*A*

(Note that as {*A*&*B*, *A*&~*B*, ~*A*} and {*A*, ~*A*} are both partitions, it follows that **p**(*A*) = **p**(*A*&*B*) + **p**(*A*&~*B*).)

How does X evaluate "If *A*, *B*"? She assumes that *A*, that is, hypothetically eliminates ~*A*. In the part of the partition that remains, in which *A* is true, *B* is four times as likely as ~*B*; that is, on the assumption that *A*, it is four to one that *B*: **p**(*B* if *A*) is 80%, **p**(~*B* if *A*) is 20%. Equivalently, as *A*&*B* is four times as likely as *A*&~*B*, **p**(*B* if *A*) is 4/5, or 80%. Equivalently, **p**(*A*&*B*) is 4/5 of **p**(*A*). In non-numerical terms: you believe that if *A*, *B* to the extent that you think that *A*&*B* is nearly as likely as *A*; or, to the extent that you think *A*&*B* is much more likely than *A*&~*B*. If you think *A*&*B* is as likely as *A*, you are certain that if *A*, *B*. In this case, your **p**(*A*&~*B*) = 0.

Go back to the truth table. You are wondering whether if *A*, *B*. Assume *A*. That is, ignore lines 3 and 4 in which *A* is false. Ask yourself about the relative probabilities of lines 1 and 2. Suppose you think line 1 is about 100 times more likely than line 2. Then you think it is about 100 to 1 that *B* if *A*.

Note: these thought-experiments can only be performed when **p**(*A*) is not 0. On this approach, indicative conditionals only have a role when the thinker takes *A* to be an epistemic possibility. If you take yourself to know for sure that Ann is in Paris, you don’t go in for "If Ann is not in Paris ..." thoughts (though of course you can think "If Ann had not been in Paris ..."). In conversation, you can pretend to take something as an epistemic possibility, temporarily, to comply with the epistemic state of the hearer. When playing the sceptic, there are not many limits on what you *can*, at a pinch, take as an epistemic possibility -- as not already ruled out. But there are some limits, as Descartes found. Is there a conditional thought that begins "If I don’t exist now ..."?

On Hook’s account, to be close to certain that if *A*, *B* is to give a high value to **p**(*A* ⊃ *B*). How does **p**(*A* ⊃ *B*) compare with $\mathbf{p}_A(B)$? In two special cases, they are equal: first, if **p**(*A*&~*B*) = 0 (and **p**(*A*) is not 0), **p**(*A* ⊃ *B*) = $\mathbf{p}_A(B)$ = 1 (i.e. 100%). Second, if **p**(*A*) = 100%, **p**(*A* ⊃ *B*) = $\mathbf{p}_A(B)$ = **p**(*B*). In all other cases, **p**(*A* ⊃ *B*) is greater than $\mathbf{p}_A(B)$. To see this we need to compare **p**(*A*&~*B*) and **p**(*A*&~*B*)/**p**(*A*). Consider

again the partition {$A\&B$, $A\&{\sim}B$, ${\sim}A$}. $\mathbf{p}(A\&{\sim}B)$ is a smaller proportion of the whole space than it is of the A-part -- the part of the space in which A is true -- except in the special cases in which $\mathbf{p}(A\&{\sim}B) = 0$, or $\mathbf{p}({\sim}A) = 0$. So, except in these special cases, $\mathbf{p}_A({\sim}B)$ is greater than $\mathbf{p}(A\&{\sim}B)$. Now $\mathbf{p}(A \supset B) = \mathbf{p}({\sim}(A\&{\sim}B))$; and $\mathbf{p}(A\&{\sim}B) + \mathbf{p}({\sim}(A\&{\sim}B)) = 1$. Also $\mathbf{p}_A(B) + \mathbf{p}_A({\sim}B) = 1$. So from $\mathbf{p}_A({\sim}B) > \mathbf{p}(A\&{\sim}B)$ it follows that $\mathbf{p}(A \supset B) > \mathbf{p}_A(B)$.

Hook and the suppositional theorist (call her Supp) come spectacularly apart when $\mathbf{p}({\sim}A)$ is high and $\mathbf{p}(A\&B)$ is much smaller than $\mathbf{p}(A\&{\sim}B)$. Let $\mathbf{p}({\sim}A) = 90\%$, $\mathbf{p}(A\&B) = 1\%$, $\mathbf{p}(A\&{\sim}B) = 9\%$. $\mathbf{p}_A(B) = 10\%$. $\mathbf{p}(A \supset B) = 91\%$. For instance, I am 90% certain that Sue won't be offered the job (${\sim}O$), and think it only 10% likely that she will decline the offer (D) if it is made, that is $\mathbf{p}_O(D) = 10\%$. $\mathbf{p}(O \supset D) = \mathbf{p}({\sim}O$ or $(O\&D)) = 91\%$.

Now let us compare Hook, Arrow, and Supp with respect to two questions raised in §2.

- Question 1. You are certain that ${\sim}(A\&{\sim}B)$, but not certain that ${\sim}A$. Should you be certain that if A, B?

  Hook: yes. Because "$A \supset B$" is true whenever $A\&{\sim}B$ is false.

  Supp: yes. Because $A\&B$ is as likely as A. $\mathbf{p}_A(B) = 1$.

  Arrow: no, not necessarily. For "$A \rightarrow B$" may be false when $A\&{\sim}B$ is false. With just the information that $A\&{\sim}B$ is false, I should not be certain that if A, B.
- Question 2. If you think it likely that ${\sim}A$, might you still think it unlikely that if A, B?

  Hook: no. "$A \supset B$" is true in all the possible situations in which ${\sim}A$ is true. If I think it likely that ${\sim}A$, I think it likely that a sufficient condition for the truth of "$A \supset B$" obtains. I must, therefore, think it likely that if A, B.

  Supp: yes. We had an example above. That most of my probability goes to ${\sim}A$ leaves open the question whether or not $A\&B$ is more probable than $A\&{\sim}B$. If $\mathbf{p}(A\&{\sim}B)$ is greater than $\mathbf{p}(A\&B)$, I think it's unlikely that if A, B. That's compatible with thinking it likely that ${\sim}A$.

  Arrow: yes. "If A, B" may be false when A is false. And I might well think it likely that that possibility obtains, i.e. unlikely that "If A, B" is true.

Supp has squared the circle: she gets the intuitively right answer to both questions. In this she differs from both Hook and Arrow. Supp's way of assessing conditionals is incompatible with the truth-functional way (they answer Question 2 differently); and incompatible with stronger-than-truth-functional truth conditions (they answer Question 1 differently). It follows that Supp's way of assessing conditionals is incompatible with the claim that conditionals have truth conditions of any kind. $\mathbf{p}_A(B)$

does not measure the probability of the truth of any proposition. Suppose it did measure the probability of the truth of some proposition *A***B*. Either *A***B* is entailed by "*A* ⊃ *B*", or it is not. If it is, it is true whenever ~*A* is true, and hence cannot be improbable when ~*A* is probable. That is, it cannot agree with Supp in its answer to Question 2. If *A***B* is not entailed by "If *A*, *B*", it may be false when ~(*A*&~*B*) is true, and hence certainty that ~(*A*&~*B*) (in the absence of certainty that ~*A*) is insufficient for certainty that *A***B*; it cannot agree with Supp in its answer to Question 1.

To make the point in a slightly different way, let me adopt the following as an expository, heuristic device, a harmless fiction. Imagine a partition as carved into a large finite number of equally-probable chunks, such that the propositions with which we are concerned are true in an exact number of them. The probability of any proposition is the proportion of chunks in which it is true. The probability of *B* on the supposition that *A* is the proportion *of the A-chunks* (the chunks in which *A* is true) which are *B*-chunks. With some misgivings, I succumb to the temptation to call these chunks "worlds": they are equally probable, mutually incompatible and jointly exhaustive epistemic possibilities, enough of them for the propositions with which we are concerned to be true, or false, at each world. The heuristic value is that judgements of probability and conditional probability then translate into statements about proportions.

Although Supp and Hook give the same answer to Question 1, their reasons are different. Supp answers "yes" *not* because a proposition, *A***B*, is true whenever *A*&~*B* is false; but because *B* is true in all the "worlds" which matter for the assessment of "If *A*, *B*": the *A*-worlds. Although Supp and Arrow give the same answer to Question 2, their reasons are different. Supp answers "yes", not because a proposition *A***B* may be false when *A* is false; but because the fact that most worlds are ~*A*-worlds is irrelevant to whether most *of the A-worlds* are *B*-worlds. To judge that *B* is true *on the supposition that A* is true, it turns out, is not to judge that something-or-other, *A***B*, is true.

By a different argument, David Lewis (1976) was the first to prove this remarkable result: there is no proposition *A***B* such that, in all probability distributions, $\mathbf{p}(A{*}B) = \mathbf{p}_A(B)$. A conditional probability does not measure the probability of the truth of any proposition. If a conditional has truth conditions, one should believe it to the extent that one thinks it is probably true. If Supp is correct, that one believes "If *A*, *B*" to the extent that one thinks it probable that *B* on the supposition that *A*, then this is not equivalent to believing some proposition to be probably true. Hence, if Supp is right, conditionals shouldn't be construed as having truth conditions at all. A conditional judgement involves two propositions, which play different roles. One is the content of a supposition. The other is the content of a judgement made under that supposition. They do not combine to yield a single proposition which is judged to be likely to be true just when the second is judged likely to be true on the supposition of the first.

Note: ways of restoring truth conditions, compatible with Supp's thesis, are considered in §4.

3.2 Validity

Ernest Adams, in two articles (1965, 1966) and a subsequent book (1975), gave a theory of the validity of arguments involving conditionals as construed by Supp. He taught us something important about

classically valid arguments as well: that they are, in a special sense to be made precise, probability-preserving. This property can be generalized to apply to arguments with conditionals. The valid ones are those which, in the special sense, preserve probability or conditional probability.

First consider classically valid (that is, necessarily truth-preserving) arguments which don't involve conditionals. We use them in arguing from contingent premises about which we are often less than completely certain. The question arises: how certain can we be of the conclusion of the argument, given that we think, but are not sure, that the premises are true? Call the improbability of a statement one minus its probability. Adams showed this: if (and only if) an argument is valid, then in no probability distribution does the improbability of its conclusion exceed the sum of the improbabilities of its premises. Call this the Probability Preservation Principle (PPP).

The proof of PPP rests on the Partition Principle -- that the probabilities of the members of a partition sum to 100% -- nothing else, beyond the fact that if *A* entails *B*, $\mathbf{p}(A\&{\sim}B) = 0$. Here are three consequences:

1. if *A* entails *B*, $\mathbf{p}(A) \leq \mathbf{p}(B)$
2. $\mathbf{p}(A \text{ or } B) = \mathbf{p}(A) + \mathbf{p}(B) - \mathbf{p}(A\&B) \leq \mathbf{p}(A) + \mathbf{p}(B)$
3. For all *n*, $\mathbf{p}(A_1 \text{ or ... or } A_n) \leq \mathbf{p}(A_1) + ... + \mathbf{p}(A_n)$

Suppose A_1, ... A_n entail *B*. Then ~*B* entails ${\sim}A_1$ or ... or ${\sim}A_n$. Therefore $\mathbf{p}({\sim}B) \leq \mathbf{p}({\sim}A_1) + ... + \mathbf{p}({\sim}A_n)$: the improbability of the conclusion of a valid argument cannot exceed the sum of the improbabilities of the premises.

The result is useful to know: if you have two premises of which you are at least 99% certain, they entitle you to be at least 98% certain of a conclusion validly drawn from them. Of course, if you have 100 premises each at least 99% certain, your conclusion may have zero probability. That is the lesson of the "Lottery Paradox". Still, Adams's result vindicates deductive reasoning from uncertain premises, provided that they are not too uncertain, and there are not too many of them.

So far, we have a very useful consequence of the classical notion of validity. Now Adams extends this consequence to arguments involving conditionals. Take a language with "and", "or", "not" and "if" -- but with "if" occurring only as the main connective in a sentence. (We put aside compounds of conditionals.) Take any argument formulated in this language. Consider any probability function over the sentences of this argument which assigns non-zero probability to the antecedents of all conditionals -- that is, any assignment of numbers to the non-conditional sentences which conforms to the Partition Principle, and to the conditional sentences which conforms to Supp's thesis: $\mathbf{p}(B \text{ if } A) = \mathbf{p}_A(B) = \mathbf{p}(A\&B)/\mathbf{p}(A)$. Let the improbability of the conditional "If *A*, *B*" be $1 - \mathbf{p}_A(B)$. *Define* a valid argument as one such that there is no probability function in which the improbability of the conclusion exceeds the sum of the improbabilities of the premises. And a nice logic emerges, which is now well known. It is the same as Stalnaker's logic over this domain (see §4.1). There are rules of proof, a decision procedure, consistency and completeness can be proved. See Adams (1998 and 1975).

I shall write the conditional which satisfies Adams's criterion of validity "$A \Rightarrow B$". We have already seen that in all distributions, $\mathbf{p}_A(B) \leq \mathbf{p}(A \supset B)$. Therefore, $A \Rightarrow B$ entails $A \supset B$: the former cannot be probable and the latter improbable. Call a non-conditional sentence a factual sentence. If an argument has a factual conclusion, and is classically valid with the conditional interpreted as $\supset$, it is valid with the conditional interpreted as the stronger $\Rightarrow$. The following patterns of inference are therefore valid:

> *A*; $A \Rightarrow B$; so *B* (modus ponens)
> $A \Rightarrow B$; ~*B*; so ~*A* (modus tollens)
> *A* or *B*; $A \Rightarrow C$; $B \Rightarrow C$; so *C*.

We cannot consistently have their premises highly probable and their conclusion highly improbable.

Arguments with conditional conclusions, however, may be valid when the conditional is interpreted as the weaker $A \supset B$, but invalid when it is interpreted as the stronger $A \Rightarrow B$. Here are some examples.

> *B*; so $A \Rightarrow B$.

I can consistently be close to certain that Sue is lecturing right now, while thinking it highly unlikely that if she had a heart attack on her way to work, she is lecturing just now.

> ~*A*; so $A \Rightarrow B$.

You can consistently be close to certain that the Republicans won't win, while thinking it highly unlikely that if they win they will double income tax.

> ~(*A*&*B*); so $A \Rightarrow$ ~*B*

I can consistently be close to certain that it's not the case that I will be hit by a bomb and injured today, while thinking it highly unlikely that if I am hit by a bomb, I won't be injured.

> *A* or *B*; so ~$A \Rightarrow B$.

As I think it is very likely to rain tomorrow, I think it's very likely to be true that it will rain or snow tomorrow. But I think it's very unlikely that if it doesn't rain, it will snow.

> $A \Rightarrow B$; so $(C\&A) \Rightarrow B$ (strengthening of the antecedent).

I can think it's highly likely that if you strike the match, it will light; but highly unlikely that if you dip it in water and strike it, it will light.

Strengthening is a special case of transitivity, in which the missing premise is a tautology: if *C*&*A* then *A*; if *A*, *B*; so if *C*&*A*, *B*. So transitivity also fails:

$A \Rightarrow B$; $B \Rightarrow C$; so $A \Rightarrow C$.

Adams gave this example (1966): I can think it highly likely that if Jones is elected, Brown will resign immediately afterwards; I can also think it highly likely that if Brown dies before the election, Jones will be elected; but I do not think it at all likely that if Brown dies before the election, Brown will resign immediately after the election!

We saw in §2.2 that Conditional Proof (CP) is invalid for any conditional stronger than $\supset$. It is invalid in Adams's logic. For instance, "~(*A*&*B*); *A*; so ~*B*" is valid. It contains no conditionals. Any necessarily truth-preserving argument satisfies PPP. If I'm close to certain that I won't be hit by a bomb and injured, *and close to certain that I will be hit by a bomb*, then I must be close to certain that I won't be injured. But, as we saw, "~(*A*&*B*); so $A \Rightarrow$ ~*B*" is invalid. Yet we can get the latter from the former by CP.

Why does CP fail on this conception of conditionals? After all, Supp's idea is to treat the antecedent of a conditional as an *assumption*. What is the difference between the roles of a premise, and of the antecedent of a conditional in the conclusion?

The antecedent of the conditional is indeed treated as an assumption. On this conception of validity, the premises are not treated as assumptions. Indeed, it is not immediately clear what it would be to treat a conditional, construed according to Supp, as an assumption: to assume something, as ordinarily understood, is to assume that it is true; and conditionals are not being construed as ordinary statement of fact. But we could approximate the idea of taking the premises as assumptions: so doing is, in most contexts, tantamount to treating them, hypothetically, as certainties. So treating the premises would be to require of a valid argument that it preserve certainty: that there must be no probability distributions in which all the premises (conditional or otherwise) are assigned 1 and the conclusion is assigned less than 1. Call this the certainty-preservation principle (CPP).

The conception of validity we have been using (PPP) takes as central the fact that premises are accepted with degrees of confidence less than certainty. Now, anything which satisfies PPP satisfies CPP. And for argument involving only factual propositions, the converse is also true: the same class of arguments necessarily preserves truth, necessarily preserves certainty and necessarily preserves probability in the sense of PPP. But arguments involving conditionals can satisfy CPP without satisfying PPP. The invalid argument forms above do preserve certainty: if you assign probability 1 to the premises, then you are constrained to assign probability 1 to the conclusion (in all probability distributions in which the antecedent of any conditional gets non-zero probability). But they do not preserve high probability. They do not satisfy PPP. If at least one premise falls short of certainty by however small an amount, the conclusion can plummet to zero.

The logico-mathematical fact behind this is the difference in logical powers between "All" and "Almost

all". If all *A*-worlds are *B*-worlds (and there are some *C*&*A*-worlds) then all *C*&*A*-worlds are *B*-worlds. But we can have: almost all *A*-worlds are *B*-worlds but no *C*&*A*-world is a *B*-world. If all *A*-worlds are *B*-worlds and all *B*-worlds are *C*-worlds, then all *A*-worlds are *C*-worlds. But we can have: all *A*-worlds are *B*-worlds, almost all *B*-worlds are *C*-worlds, yet no *A*-world is a *C*-world; just as we can have, all kiwis are birds, almost all birds fly, but no kiwi flies.

Someone might react as follows: "All I want of a valid argument is that it preserve certainty. I'm not bothered if an argument can have premises close to certain and a conclusion far from certain, as long as the conclusion is certain when the premises are certain".

We *could* use the word "valid" in such a way that an argument is valid provided it preserves certainty. If our interest in logic is confined to its application to mathematics or other a priori matters, that is fine. Further, when our arguments do not contain conditionals, if we have certainty-preservation, probability-preservation comes free. But if we use conditionals when arguing about contingent matters, then great caution will be required. Unless we are 100% certain of the premises, the arguments above which are invalid on Adams's criterion guarantee nothing about what you are entitled to think about the conclusion. The line between 100% certainty and something very close is hard to make out: it's not clear how you tell which side of it you are on. The epistemically cautious might admit that they are never, or only very rarely, 100% certain of contingent conditionals. So it would be useful to have another category of argument, the "super-valid", which preserves high probability as well as certainty. Adams has shown us which arguments (on Supp's reading of "if") are super-valid.

4. Truth Conditions Revisited: Stalnaker and Jackson

4.1 Stalnaker

Adams's theory of validity emerged in the mid-1960s. "Nearest possible worlds" theories were not yet in evidence. Nor was Lewis's result that conditional probabilities are not probabilities of the truth of a proposition. (Adams expressed scepticism about truth conditions for conditionals, but the question was still open.) Stalnaker's (1968) semantics for conditionals was an attempt to provide truth conditions which were compatible with Ramsey's and Adams's thesis about conditional belief. (See also Stalnaker (1970)). That is, he sought truth conditions for a proposition *A*>*B* (his notation) such that $\mathbf{p}(A>B)$ must equal $\mathbf{p}_A(B)$:

> Now that we have found an answer to the question, "How do we decide whether or not we believe a conditional statement?" [Ramsey's and Adams's answer] the problem is to make the transition from belief conditions to truth conditions; ... . The concept of a *possible world* is just what we need to make the transition, since a possible world is the ontological analogue of a stock of hypothetical beliefs. The following ... is a first approximation to the

> account I shall propose: Consider a possible world in which *A* is true and otherwise differs minimally from the actual world. *"If A, then B" is true (false) just in case B is true (false) in that possible world*. (1968, pp. 33-4)

If an argument is necessarily truth-preserving, the improbability of its conclusion cannot exceed the sum of the improbabilities of the premises. The latter was the criterion Adams used in constructing his logic. So Stalnaker’s logic for conditionals must agree with Adams’s over their common domain. And it does. The argument forms we showed to be invalid in Adams’s logic (§3.2) are invalid on Stalnaker’s semantics. For instance, the following is possible: in the nearest possible world in which you strike the match, it lights; in the nearest world in which you dip the match in water and strike it, it doesn’t light. So Strengthening fails. (By "nearest world in which ..." I mean the possible world which is minimally different from the actual world in which ... .)

Conditional Proof fails for Stalnaker’s semantics. "*A* or *B*; ~*A*; so *B*" is of course valid. But (*) "*A* or *B*, therefore ~*A*>*B*" is not: it can be true that Ann or Mary cooked the dinner (for Ann cooked it); yet false that in the nearest world to the actual world in which Ann did not cook it, Mary cooked it.

Stalnaker (1975) tried to show that although the above argument form (*) is invalid, it is nevertheless a "reasonable inference" when "*A* or *B*" is assertable, that is, when the speaker has ruled out ~*A*&~*B*, but ~*A*&*B* and *A*&~*B* remain open possibilities. Indicative conditionals, he claims, are used only when their antecedents are epistemically possible for the speaker (here he agrees with Supp). Then comes the crucial claim: *worlds which are epistemically possible for the speaker count as closer to the actual world than those which are not*. All ~*A*&~*B*-worlds have been eliminated. Not all ~*A*&*B*-worlds have been eliminated. All the speaker’s epistemically possible ~*A*-worlds are *B*-worlds. So the nearest ~*A*-world is a *B*-world. "*A*>*B*" is true.

This makes the truth conditions of a conditional, e.g. "If Ann didn’t cook the dinner, Bob cooked it" *dependent on what the speaker believes*. All that is common to different utterances of "*A*>*B*" is that they say that a certain *A*-world is a *B*-world. That is not news: provided that *A* and *B* are compatible, some *A*-world is a *B*-world. Which world is being said to be a *B*-world depends on the speaker’s beliefs. With fixed meanings for *A* and *B*, there is no single proposition *A*>*B*, but a different one for each belief state: we might write $A>_{p}B$, where "p" is a probability function indexed to a person and a time.

This enables Stalnaker to avoid the argument against non-truth-functional truth conditions given in §2.2. The argument was as follows. There are six incompatible logically possible combinations of truth values for *A*, *B* and ~*A* → *B*. You start off with no firm beliefs about which obtains. Now you eliminate ~*A*&~*B*, i.e. establish *A* or *B*. That leaves five remaining possibilities, including two in which "~*A* → *B*" is false. So you can’t be certain that ~*A* → *B*. Stalnaker replies: you can’t, indeed, be certain that the proposition you were wondering about earlier is true. But in your new epistemic state, you express a new proposition by "~*A* → *B*", with different truth conditions, governed by a new nearness relation, and you know that that new proposition is true.

Disagreement and change of mind give way to equivocation. Suppose you and I start off knowing *A* or *B* or *C*. You then eliminate *C*. You accept "If ~*A*, *B*" and reject "If ~*A*, *C*". I eliminate *B*. I accept "If ~*A*, *C*", and reject "If ~*A*, *B*". I assent to a sentence from which you dissent, and vice versa. We do not disagree. We express different propositions, with different truth conditions, governed by our different epistemic states. Worlds which are near for me are far for you.

Are belief-relative truth conditions better than no truth conditions? They account for the validity of arguments; but Adams's logic has its own rationale, without them. They account for sentences with conditional constituents. But we saw (§2.4) that they sometimes give counterintuitive results. Are we able to escape Lewis's result that a conditional probability is not the probability of the truth of a proposition, by making the proposition dependent on the believer's epistemic state? Lewis showed that there is no proposition $A*B$ such that in every belief state $\mathbf{p}(A*B) = \mathbf{p}_A(B)$. He did not rule out that in every belief state there is some proposition or other, $A*B$, such that $\mathbf{p}(A*B) = \mathbf{p}_A(B)$. However, in the wake of Lewis, Stalnaker himself proved this stronger result, for his conditional connective: the equation $\mathbf{p}(A>B) = \mathbf{p}_A(B)$ cannot hold for all propositions in a single belief state. If it holds for *A* and *B*, we can find two other propositions, *C* and *D* (truth-functional compounds of *A*, *B* and $A>B$) for which, demonstrably, it does not hold. (See Stalnaker's letter to van Fraassen published in van Fraassen (1976, pp. 303-4), Gibbard (1981, pp. 219-20), and Edgington (1995, pp. 276-8).)

It was Gibbard (1981, pp. 231-4) who showed just how belief-sensitive Stalnaker's truth conditions would be. Later (1984), Stalnaker abandoned the claim that conditionals express belief-relative propositions, writing "It follows that the conditional ... expresses one proposition when it is asserted, and a different one when it is denied" (p. 110).

4.2 Jackson

Frank Jackson holds that "If *A*, *B*" has the truth conditions of "$A \supset B$", i.e. "~*A* or *B*"; but it is part of its meaning that it is governed by a special rule of assertability. "If" is assimilated to words like "but", "nevertheless" and "even". "*A* but *B*" has the same truth conditions as "*A* and *B*", yet they differ in meaning: "but" is used to signal a contrast between *A* and *B*. When *A* and *B* are true and the contrast is lacking, "*A* but *B*" is true but inappropriate. Likewise, "Even John can understand this proof" is true when John can understand this proof, but inappropriate when John is a world-class logician.

According to Jackson, in asserting "If *A*, *B*" the speaker expresses his belief that $A \supset B$, and also indicates that this belief is "robust" with respect to the antecedent *A*. In Jackson's early work (1979, 1980) "robustness" was explained thus: the speaker would not abandon his belief that $A \supset B$ if he were to learn that *A*. This, it was claimed, amounted to the speaker's having a high probability for $A \supset B$ given *A*, i.e. for (~*A* or *B*) given *A*, which is just to have a high probability for *B* given *A*. Thus, assertability goes by conditional probability. Robustness was meant to ensure that an assertable conditional is fit for modus ponens. Robustness is not satisfied if you believe $A \supset B$ solely on the grounds that ~*A*. Then, if you discover that *A*, you will abandon your belief in $A \supset B$ rather than conclude that *B*.

Jackson came to realise, however, that there are assertable conditionals which one would not continue to believe if one learned the antecedent. I say "If Reagan worked for the KGB, I'll never find out" (Lewis's example (1986, p. 155)). My conditional probability for consequent given antecedent is high. But if I were to discover that the antecedent is true, I would abandon the conditional belief, rather than conclude that I will never find out that the antecedent is true. So, in Jackson's later work (1987), robustness with respect to *A* is simply defined as $\mathbf{p}_A(A \supset B)$ being high, which is trivially equivalent to $\mathbf{p}_A(B)$ being high. In most cases, though, the earlier explanation will hold good.

What do we need the truth-functional truth conditions for? Do they explain the meaning of compounds of conditionals? According to Jackson, they do not (1987, p. 129). We know what "$A \supset B$" means, as a constituent in complex sentences. But "$A \supset B$" does not mean the same as "If *A*, *B*". The latter has a special assertability condition. And his theory has no implications about what, if anything, "if *A*, *B*" means when it occurs, unasserted, as a constituent in a longer sentence.

(Here his analogy with "but" etc. fails. "But" can occur in unasserted clauses: "Either he arrived on time but didn't wait for us, or he never arrived at all" (see Woods (1997, p. 61)). It also occurs in questions and commands: "Shut the door but leave the window open". "Does anyone want eggs but no ham?". "But" means "and in contrast". Its meaning is not given by an "assertability condition".)

Do the truth-functional truth conditions explain the validity of arguments involving conditionals? Not in a way that accords well with intuition, we have seen. Jackson claims that our intuitions are at fault here: we confuse preservation of truth and preservation of assertability (1987, pp. 50-1).

Nor is there any direct evidence for Jackson's theory. Nobody who thinks the Republicans won't win treats "If the Republicans win, they will double income tax" as inappropriate but probably true, in the same category as "Even Gödel understood truth-functional logic". Jackson is aware of this. He seems to advocate an error theory of conditionals: ordinary linguistic behaviour fits the false theory that there is a proposition $A*B$ such that $\mathbf{p}(A*B) = \mathbf{p}_A(B)$ (1987, pp. 39-40). If this is his view, he cannot hold that his own theory is a psychologically accurate account of what people do when they use conditionals. Perhaps it is an account of how we *should* use conditionals, and would if we were free from error: we *should* accept that "If the Republicans win they will double income tax" is probably true when it is probable that the Republicans won't win. Would we gain anything from following this prescription? It is hard to see that we would: we would deprive ourselves of the ability to discriminate between believable and unbelievable conditionals whose antecedents we think false.

4.3 Compounds

A common complaint against Supp's theory is that if conditionals do not express propositions with truth conditions, we have no account of the behaviour of compound sentences with conditionals as parts (see e.g. Lewis (1976, p. 142)). However, no theory has an intuitively adequate account of compounds of conditionals: we saw in §2.4 that there are compounds which Hook gets wrong; and compounds which Arrow gets wrong. Grice's and Jackson's defences of Hook focus on what more is needed to justify the

assertion of a conditional, beyond belief that it is true. This is no help when it occurs, unasserted, as a constituent of a longer sentence, as Jackson accepts. And with negations of conditionals and conditionals in antecedents, we saw, the problem is reversed: we assert conditionals which we would not believe if we construed them truth-functionally.

There have been ambitious attempts to construct a general theory of compounds of conditionals, compatible with Supp's thesis. They are based on a partial restoration of truth values, which has some merit. Note that the difficulties for Hook and Arrow in §§2 and 3 were focused on the last two lines of the truth table -- the cases in which the antecedent is false. No problems arose in virtue of the cases in which the antecedent is true. Perhaps we can say that "If *A*, *B*" is true when *A* and *B* are both true, is false when *A* is true and *B* is false, and has no truth value when *A* is false. We must immediately add that to believe (or assert) that if *A*, *B*, is not to believe (assert) that it is true; for it is true only if *A*&*B*; and one might believe that if *A*, *B*, and properly assert it, without believing that *A*&*B* -- indeed, while thinking that it is very likely not true. If I say "If you press that button, there will be an explosion", I hope and expect that you will not press it, and hence that my remark is not true.

Instead, one must say that to believe "If *A*, *B*" is to believe that it is true *rather than false*; it is to believe that *A*&*B* is much more likely than *A*&~*B*; i.e., to believe that it is true given that it is true or false. This is just to say that one's confidence in a conditional is measured by $\mathbf{p}_A(B)$. Note that for a bivalent proposition, belief that it is true coincides with belief that it is true rather than false. But the latter, not the former, generalizes to conditionals.

This has some minor advantages. It allows one to be right by luck, and wrong by bad luck: however strong my grounds for thinking that *B* if *A*, if it turns out that *A*&~*B*, I was wrong. However poor my grounds, if it turns out that *A*&*B*, I was vindicated.

Now in principle one could handle negations, conjunctions and disjunctions of conditionals by three-valued truth tables; and continue to say that a complex statement is believable to the extent that it is judged probably true given that it is true or false. For a conjunction, $((A \Rightarrow B)\&(C \Rightarrow D))$, the most natural truth table would seem to be: the conjunction is true iff both conjuncts are true; false iff at least one conjunct is false; otherwise it lacks a truth value. This has unappetizing consequences. Consider a conjunction of two conditionals whose antecedents are *A* and ~*A* respectively, such that the first conditional is 100% certain and the second 99% certain, for instance, $((A \Rightarrow A)\&(\sim A \Rightarrow B))$ where $\mathbf{p}_{\sim A}(B)$ = 0.99. This looks like something about which you should be close to certain. But it cannot be true (for one of the antecedents is false), and it may be false, in the unlucky event that it turns out that ~*A*&~*B*. So the probability of its truth, given that it has a truth value, is 0. One can try other truth tables: make the conjunction true provided that it has at least one true conjunct and no false conjunct, false if it has at least one false conjunct, lacking truth value otherwise. And one can come up with equally unappetizing consequences. For work in this tradition and valuable surveys of related work, see McDermott (1996) and Milne (1997).

A variant of this approach gives "semantic values" to conditionals as follows: 1 (= true) if *A*&*B*; 0 (=

false) if A&~B; $\mathbf{p}_A(B)$ if ~A. Thus we have a belief-relative three-valued entity. Its probability is its "expected value". For instance, I'm to pick a ball from a bag. 50% of the balls are red. 80% of the red balls have black spots. Consider "If I pick a red ball (R) it will have a black spot (B)". $\mathbf{p}_R(B)$ = 80%. If R&B, the conditional gets semantic value 1, if R&~B, it gets semantic value 0. What does it get if ~R? One way of motivating this approach is to treat it as a refinement of Stalnaker's truth conditions. Is the nearest R-world a B-world or not? Well, if I actually don't pick a red ball, there isn't any difference, in nearness to the actual world, between the worlds in which I do; but 80% of them are B-worlds. Select an R-world at random; then it's 80% likely that it is a B-world. So "If R, B" gets 80% if ~R. You don't divide the ~R-worlds into those in which "If R, B" is true and those in which it is false. Instead you make the conditional "80%-true" in all of them. The expected value of "If R, B" is $(\mathbf{p}(R\&B) \times 1) + (\mathbf{p}(R\&{\sim}B) \times 0) + (\mathbf{p}({\sim}R) \times 0.8)) = (0.4 \times 1) + (0.1 \times 0) + (0.5 \times 0.8) = 0.8 = \mathbf{p}_R(B)$. Ways of handling compounds of conditionals have been proposed on the basis of these semantic values. But again, they sometimes give implausible results. For developments of this approach, see van Fraassen (1976), McGee (1989), Jeffrey (1991), Stalnaker and Jeffrey (1994). For some counterintuitive consequences, see Edgington (1991, pp. 200-2), Lance (1991), McDermott (1996, pp. 25-28).

Thus, no general algorithmic approach to complex statements with conditional components has yet met with success. Many followers of Adams take (by default) a more relaxed approach to the problem. They try to show that when a sentence with a conditional subsentence is intelligible, it can be paraphrased, at least in context, by a sentence without a conditional subsentence. As conditionals are not ordinary propositions, in that they essentially involve suppositions, this (it is claimed) is good enough. They also point out that some constructions are rarer, and harder to understand, and more peculiar, than would be expected if conditionals had truth conditions and embedded in a standard way. See Appiah (1985, pp. 205-10), Gibbard (1981, pp. 234-8), Edgington (1995, pp. 280-4), Woods (1997, pp. 58-68 and 120-4); see also Jackson (1987, pp. 127-37).

For some constructions the paraphrase can be done in a general, uniform way. For example, "If A, then if B, C" can be paraphrased "If A&B, C". "It's not the case that if A, B" is probably best paraphrased as "If A, it's not the case that B". The alternative would be something like "If A, it might well be the case that ~B", expressing the judgement that the probability of B given A is not particularly high. But with a categorical statement, like "It will rain today", it is when one disagrees strongly that one says "No it won't" or "It's not the case that it will rain today". When one disagrees weakly, one says something like "It might well not" or "I wouldn't be so sure". By analogy, then, it seems that it is strong disagreement with "If A, B" that deserves the negation operator. If someone asserts two or more conditionals joined by "and", each conditional can be assessed as a separate assertion.

Disjunctions of conditionals are peculiar. Of course, it is a sufficient condition for accepting such a disjunction that one accepts one disjunct. But this is rather uninteresting. "Or" is a very useful word when it connects things we are uncertain about, for often we can be confident that A or B, while not knowing which. We are often uncertain about conditionals. Yet "Either (if A, B) or (if C, D) -- but I don't know which" is a form of thought that is rarely if ever instantiated in real life. If conditionals are ordinary statements of fact, this is odd. The problem is not merely one of syntactic complexity: "Either (A&B) or

(*C*&*D*) -- I don’t know which" is just as syntactically complex, but is quite commonplace. Several agile minds have risen to the challenge of providing me with examples of the kind I claim are virtually non-existent: "Either, if I go out I’ll get wet, or, if I turn the television on I’ll see tennis -- I don’t know which": for, either it’s raining or it isn’t. If it’s raining and I go out, I’ll get wet. If it isn’t raining and I turn the television on I’ll see tennis. "Either, if you open box *A*, you’ll get ten dollars, or, if you open box *B*, you’ll get a button -- I don’t know which"; for, if Fred is in a good mood he has put ten dollars in box *A* and twenty dollars in box *B*; if Fred is not in a good mood he has put a paper clip in box *A* and a button in box *B*. All right. But the disjunction of conditionals is an exceedingly bad way of conveying the information you have, and once the necessary background is filled in, we see that the disjunction belongs elsewhere. So we have little use for them. On the other hand, our genuine need for disjunctions shows up naturally inside a conditional "If *A*, either *B* or *C* (I don’t know which)". Some apparent disjunctions of conditionals are really no such thing: "Either we’ll have fish, if John arrives, or we’ll have leftovers, if he doesn’t". Note that both disjuncts are asserted. Note that it doesn’t seem to matter whether one uses "or" or "and" in "If it’s fine, we’ll have a picnic, or [and] if it isn’t, we’ll go to the movies". I conclude that disjunctions proper of conditionals are of little use -- the best we can do, with my early examples, is to discern some disjunction of categorical propositions each disjunct of which supports one or other conditional.

Conditionals in antecedents are also problematic. Gibbard suggests (1981, pp. 234-8) that we have no general way of decoding them, and some cannot be deciphered, for example, said of a recent conference, "If Kripke was there if Strawson was there, then Anscombe was there". "Do you know what you have been told?", he asks (p. 235). When we do understand utterances of this form, he suggests, it is because we can identify some obvious basis, *D*, for an assertion of "If *A*, *B*" and interpret "If (*B* if *A*), *C*" as "If *D*, *C*". For instance, "If the light will go on if you press the switch, the electrician has come": if the power is on, the electrician has come.

As said above, "If *A*, then if *B*, *C*" is to be paraphrased as "If *A*&*B*, then *C*". For to suppose that *A*, then to suppose that *B* and make a judgement about *C* under those suppositions, is the same as to make a judgement about *C* under the supposition that *A*&*B*. Let’s consider this as applied to a problem raised by McGee (1985) with the following example. Before Reagan’s first election, Reagan was hot favourite, a second Republican, Anderson, was a complete outsider, and Carter was lagging well behind Reagan. Consider first

> (1) If a Republican wins and Reagan does not win, then Anderson will win.

As these are the only two Republicans in the race, (1) is unassailable. Now consider

> (2) If a Republican wins, then if Reagan does not win, Anderson will win.

We read (2) as equivalent to (1), hence also unassailable.

Suppose I’m close to certain (say, 90% certain) that Reagan will win, and hence close to certain that

(3) A Republican will win.

But I don’t believe

(4) If Reagan does not win, Anderson will win.

I’m less than 1% certain that (4). On the contrary, I believe that if Reagan doesn’t win, Carter will win. As these opinions seem sensible, we have a prima facie counterexample to modus ponens: I accept (2) and (3), but reject (4). Truth conditions or not, valid arguments obey the probability-preservation principle. I’m 100% certain that (2), 90% certain that (3), but less than 1% certain that (4).

Hook saves modus ponens by claiming that I must accept (4). For Hook, (4) is equivalent to "Either Reagan will win or Anderson will win". As I’m 90% certain that Reagan will win, I must accept this disjunction, and hence accept (4). Hook’s reading of (4) is, of course, implausible.

Arrow saves modus ponens by claiming that, although (1) is certain, (2) is not equivalent to (1), and (2) is almost certainly false. For Stalnaker,

(5) If a Republican wins, then if Reagan doesn’t win, Carter will win

is true. To assess (5), we need to consider the nearest world in which a Republican wins (call it *w*), and ask whether the conditional consequent is true at *w*. At *w*, almost certainly, it is Reagan who wins. We need now to consider the nearest world to *w* in which Reagan does not win. Call it w'. In w', almost certainly, Carter wins.

Stalnaker’s reading of (2) is implausible; intuitively, we accept (2) as equivalent to (1), and do not accept (5).

Supp saves modus ponens by denying that the argument is really of that form. "$A \Rightarrow B$; *A*; so *B*" is demonstrably valid when *A* and *B* are propositions. For instance, if $\mathbf{p}(A)$ = 90% and $\mathbf{p}_A(B)$ = 90% the lowest possible value for $\mathbf{p}(B)$ is 81%. The "consequent" of (2), "If Reagan doesn’t win, Anderson will win", is not a proposition. The argument is really of the form "If *A*&*B*, then *C*; *A*; so if *B* then *C*". This argument form is invalid (Supp and Stalnaker agree). Take the case where *C* = *A*, and we have "If *A*&*B* then *A*; *A*; so if *B* then *A*". The first premise is a tautology and falls out as redundant; and we are left with "*A*; so if *B* then *A*". We have already seen that this is invalid: I can think it very likely that Sue is lecturing right now, without thinking that if she was injured on her way to work, she is lecturing right now.

Compounds of conditionals are a hard problem for everyone. It is difficult to see why it should be so hard if conditionals have truth conditions. Supp is not at a unilateral disadvantage.

5. Other Conditional Speech Acts and Propositional Attitudes

As well as conditional beliefs, there are conditional desires, hopes, fears, etc.. As well as conditional statements, there are conditional commands, questions, offers, promises, bets, etc.. "If he calls" plays the same role in "If he calls, what shall I say?", "If he calls, tell him I'm out" and "If he calls, Mary will be pleased". Which of our theories extends to these other kinds of conditional?

One believes that *B* to the extent that one thinks *B* more likely than not *B*; according to Supp, one believes that *B* if *A* to the extent that one believes that *B* under the supposition that *A*, i.e. to the extent that one thinks *A*&*B* more likely than *A*&~*B*; and there is no proposition *X* such that one must believe *X* more likely than ~*X*, just to the extent that one believes *A*&*B* more likely than *A*&~*B*. Conditional desires appear to be like conditional beliefs: to desire that *B* is to prefer *B* to ~*B*; to desire that *B* if *A* is to prefer *A*&*B* to *A*&~*B*; there is no proposition *X* such that one prefers *X* to ~*X* just to the extent that one prefers *A*&*B* to *A*&~*B*. I have entered a competition and have a very small chance of winning. I express the desire that if I win the prize (*W*), you tell Fred straight away (*T*). I prefer *W*&*T* to *W*&~*T*. I do not necessarily prefer ($W \supset T$) to ~($W \supset T$), i.e. (~*W* or *W*&*T*) to *W*&~*T*. For I also want to win the prize, and much the most likely way for (~*W* or *W*&*T*) to be true is that I don't win the prize. Nor is my conditional desire satisfied if I don't win but in the nearest possible world in which I win, you tell Fred straight away.

If I believe that *B* if *A*, i.e. (according to Supp) think *A*&*B* much more likely than *A*&~*B*, this puts me in a position to make a conditional commitment to *B*: to assert that *B*, conditionally upon *A*. If *A* is found to be true, my conditional assertion has the force of an assertion of *B*. If *A* is false, there is no proposition that I asserted. I did, however, express my conditional belief -- it is not as though I said nothing. Suppose I say "If you press that switch, there will be an explosion", and my hearer takes me to have made a conditional assertion of the consequent, one which will have the force of an assertion of the consequent if she presses the button. Provided she takes me to be trustworthy and reliable, she thinks that if she presses the switch, the consequent is likely to be true. That is, she acquires a reason to think that if she presses it, there will be an explosion; and hence a reason not to press it.

Conditional commands can, likewise, be construed as having the force of a command of the consequent, conditional upon the antecedent's being true. The doctor says to the nurse in the emergency ward, "If the patient is still alive in the morning, change the dressing". Considered as a command to make Hook's conditional true, this is equivalent to "Make it the case that either the patient is not alive in the morning, or you change the dressing". The nurse puts a pillow over the patient's face and kills her. On the truth-functional interpretation, the nurse can claim that he was carrying out the doctor's order. Extending Jackson's account to conditional commands, the doctor said "Make it the case that either the patient is not alive in the morning, or you change the dressing", and indicated that she would still command this if she knew that the patient would be alive. This doesn't help. The nurse who kills the patient still carried out an order. Why should the nurse be concerned with what the doctor would command in a counterfactual situation?

Hook will reply to the above argument about conditional commands that we need to appeal to pragmatics. Typically, for any command, conditional or not, there are tacitly understood reasonable and unreasonable ways of obeying it; and killing the patient is to be tacitly understood as a totally unreasonable way of making the truth-functional conditional true -- as, indeed, would be changing the dressing in such an incompetent way that you almost strangle the patient in the process. The latter clearly is obeying the command, but not in the intended manner. But it is stretching pragmatics rather far to say the same of the former. To take a less dramatic example, at Fred's request, the Head of Department agrees to bring it about that he gives the Kant lectures if his appointment is extended. She then puts every effort into making sure that his appointment is not extended. Is it plausible to say that this is doing what she was asked to do, albeit not in the intended way?

Extending Stalnaker's account to conditional commands, "If it rains, take your umbrella" becomes "In the nearest possible world in which it rains, take your umbrella". Suppose I have forgotten your command or alternatively am inclined to disregard it. However, it doesn't rain. In the nearest world in which it rains, I don't take my umbrella. On Stalnaker's account, I disobeyed you. Similarly for conditional promises: on this analysis I could break my promise to go to the doctor if the pain gets worse, even if the pain gets better. This is wrong: conditional commands and promises are not requirements on my behaviour in other possible worlds.

Among conditional questions we can distinguish those in which the addressee is presumed to know whether the antecedent is true, and those in which he is not. In the latter case, the addressee is being asked to suppose that the antecedent is true, and give his opinion about the consequent: "If it rains, will the match be cancelled?". In the former case -- "If you have been to London, did you like it?" -- he is expected to answer the consequent-question if the antecedent is true. If the antecedent is false, the question lapses: there is no conditional belief for him to express. "Not applicable" as the childless might write on a form which asks "If you have children, how many children do you have?". You are not being asked how many children you have in the nearest possible world in which you have children. Nor is it permissible to answer "17" on the grounds that "I have children ⊃ I have 17 children" is true. Nor are you being asked what you would believe about the consequent if you came to believe that you did have children.

Widening our perspective to include these other conditionals tends to confirm Supp's view. Any propositional attitude can be held categorically, or under a supposition. Any speech act can be performed unconditionally, or conditionally upon something else. Our uses of "if", on the whole, seem to be better and more uniformly explained without invoking conditional propositions.

Comparative Philosophy, Chinese and Western

Comparative philosophy brings together philosophical traditions that have developed in relative isolation from one another and that are defined quite broadly along cultural and regional lines -- Chinese versus Western, for example. Several main issues about the commensurability of philosophical traditions make up the subject matter of comparative philosophy. One issue is methodological commensurability -- whether and how comparisons between different philosophical traditions, in this case the Chinese and Western, are to be conducted. Views run the gamut from those holding that meaningful comparisons cannot be conducted at all to those holding that the content of traditions must largely be the same. Other issues concerning commensurability concern specific subject matters of traditions. The issue of metaphysical and epistemological commensurability involves the comparison of traditions on their conceptions of the real and their modes of inquiry and justification. Ethical commensurability involves the comparison of these traditions on the matters of how people ought to live their lives, whether both traditions have moralities and if so how similar and dissimilar they are. The separation between these main issues is somewhat artificial, given that a discussion of methodological commensurability will inevitably involve the comparison of traditions on metaphysical, epistemological, and ethical matters. There is some heuristic value, however, in beginning with a general discussion of views on methodological commensurability with a brief illustration of how these views might be applied to some Chinese/Western comparisons. Subsequent sections will address Chinese-Western comparisons in metaphysics, epistemology, and ethics that have assumed special prominence in the literature.

Doing comparative philosophy well can be very difficult because of the vast range of texts and their intellectual and historical contexts it requires its practioners to cover. Oversimplifications, excessively stark contrasts, and illicit assimilations count as the most frequent sins. One benefit of comparative philosophy lies in the way that it forces reflection on the most deeply entrenched and otherwise unquestioned agendas and assumptions of one's own tradition. Another benefit at which its practioners often aim is that the traditions actually interact and enrich one another. Demands for rigor and depth of scholarship obviously rank as some of the most important standards applying to philosophy inquiry. The task of meeting these standards becomes more manageable as the field of inquiry narrows. Such a result can be legitimate but sometimes myopic and impoverishing.

---

1. Methodological Commensurability

Those arguing for radical incommensurability -- the view that the questions and answers in one tradition cannot sustain meaningful statement in the other tradition -- rely on the recognition of radical difference in basic concepts and modes of inquiry. Given such radical differences, they argue, there can be no cross-traditional reference to a common subject matter and to a truth about that subject matter that is independent of the basic conceptual vocabulary and theories and justificatory practices of a particular tradition (see Rorty, 1989, and Shweder, 1989). Looking for a possible Chinese-Western instance of radical incommensurability, one might go to Daoist texts such as the *Daodejing* and the *Zhuangzi*. When it is said in chapter one (as traditionally arranged and on one translation) of the *Daodejing* that "The Way that can be spoken of is not the constant Way," or in chapter two that the "sages abide in nonaction and practice the teaching that is without words," one is finding something different from the usual in Western texts infused with ideals of discursive rationality and argumentation. Or consider the *Lunyu* or *Analects* 1:2, where the importance of rightly ordered family relations is emphasized for right order in the state ("He who has grown to be a filial son and respectful younger brother will be unlikely to defy his superiors and there has never been the case of someone inclined to defy his superiors and stir up a rebellion"). The prominent and enduring place of this theme of state as family writ large sets that tradition apart from Western contractual traditions that have come to emphasize right order in the state as that which can be ratified by an uncoerced agreement among equals concerned to protect their private interests. Opponents of radical incommensurability will level the charge that it presupposes a hyperdramatic contrast between traditions. For example, the Western tradition has not lacked for skeptics on the power of discusive rationality, and some of these skeptics have nevertheless believed in a mode of veridical access to something of supreme significance -- to a powerful experience within themselves or to something much larger outside themselves. At the same time, it must be noted that the positive theme is more recessive in the Western tradition and appears mainly in theistic versions, as it does in Plotinus (*Enneads*), Meister Eckhart (*Von unsagbaren Dingen*) and Hildegaard of Bingen (*Scivias*). Similarly, the Western tradition has certainly housed strains of thought that do view the state as more of a natural outgrowth of small human groups such as family and community. Even a major modern figure such as David Hume (*Treatise of Human Nature*, 3.2.2) explicitly rejects the idea of contract as central to understanding the origin or justification of social and political bonds. There might still be a difference between Chinese and Western traditions with respect to which strains of thought become dominant or at least prevalent, but that difference does not appear to come under the heading of radical incommensurability..

Samuel Fleischacker (1992) proposes a more moderate version of incommensurability -- sometimes we can understand others just well enough to know that we don't understand them. His argument has roots in

Wittgenstein's view that knowledge depends on a background of shared assumptions and standards of evidence. "World pictures" are embedded within cultures. Our world picture involves not only a distinctive set of beliefs about the world but also an ordering of interests that determines how we go about trying to have reliable beliefs. This ordering differs from those dominant in other cultures. We in the West have given precedence to our interests in "egalitarian knowledge" (wanting and believing that people have roughly equal access to the truth) and in prediction and control of this-worldly objects. The world pictures of other cultures embody other interests, and we may not be able to prove that they are wrong, or indeed, we may be unable to fully understand why it is that they value the interests they value so highly. Nevertheless, we understand that they do value these interests highly and think they are wrong to do so. We make such judgments despite our merely partial understanding because we tend to see a certain set of interests as the proper guide for a minimally decent or sensible human life.

The idea that the distinctive character of a "world picture" lies partly in the interests they embody seems plausible. Daoism and Confucianism, at least after a certain stage in the development of these schools, exemplify the way that a set of interests intertwine with beliefs about the world. Both schools exemplify in different ways a conception of understanding the world that is inseparable from the interest in coming into "attunement" with it, to use a felicitous word from Charles Taylor (1982). To become attuned to the world is to see its goodness and to know one's place in the order of the world. To say that Daoists exemplify this theme about seeing the goodness of the world is in a way misleading, since there is in the *Daodejing* and *Zhuangzi* a profound mistrust of our conceptual separations between opposites such as good and bad. However, as has been noted many times, the notion of "nonaction" or *wuwei* does not denote literal inaction but presupposes something like the possibility of an unforced acting *with* the grain of things, and that presupposes that it is possible to become attuned to that grain while in a state of awareness that is not cluttered by distorting conceptual oppositions. Both Daoist texts straightforwardly recommend *wuwei* and in this sense presuppose the goodness of the world and the way its "grain" goes. Confucian texts uphold the ideal of a different kind of attunement, under which the world and its order can be called good without the ambiguity that Daoist skepticism with conceptual opposition creates. For example, the *Mencius* (the name is actually a latinization given by Christian priests for '*Mengzi*') presents a theory that human nature contains the germs or sprouts of goodness, tendencies to certain feelings and judgments such as manifested by the feeling of compassion for a child about to fall into a well. These sprouts are in human nature because they were sent by *tian* (literally meaning 'sky' but most often translated as 'Heaven' and perhaps best conceived as an impersonal ordering force of the universe). Taylor thinks that modern science has severed the connection between understanding and attunement. In Fleischacker's terms, modern science is predicated on different interests, prediction and control foremost among these interests. Taylor believes that the severance of understanding and attunement resulted in superior understanding at least of physical nature. But as he is careful to point out, no single argument can prove global superiority. If we can take attunement as an ideal, we have failed miserably, even as our technological control of nature has increased immeasurably. Perhaps, then, the contrast between a Chinese world picture in which attunement figures prominently and a modern scientific view predicated on the interests of prediction and control serves as an example of the sort of moderate incommensurability Fleischacker has in mind. One question to be raised about this kind of incommensurability, however, is whether it truly involves lack of understanding between traditions. Taylor himself draws examples of the theme of attunement from Plato and the European cultural tradition. Do we really fail to understand the

appeal behind world pictures of attunement? Taylor's complex assessment suggests no inability on our part to understand the force behind both kinds of world pictures. Even to take the stance that attunement pictures are comforting illusions (an assessment less complex than the one Taylor adopts) is to suppose that one does understand the appeal behind them.

A different kind of incommensurability that may arise is not incomprehensibility between traditions but lack of common standards sufficient for settling significant conflicts between them. Alasdair MacIntyre (1988, 1989) has illustrated the difference between being able to understand a tradition and being able to translate all its claims into the language of another tradition by pointing to the possibility of "bilinguals" -- people who, for example, might have been raised within one community and its tradition, and then through migration or conquest, become a member of another community and its different tradition. Such bilinguals might very well understand each tradition, and such understanding might include knowledge of those parts of each that cannot be translated into the language of the other. Such bilinguals would not encounter the sort of radical incommensurability constituted by incomprehensibility, but they may be *unable to resolve conflicts of belief* between the traditions, instead having to relativize the claims of each in some such form as "seems true to this particular community" or "seems justified to this particular community." This kind of "evaluational" incommensurability, rather than meaning incommensurability, might fit better the case of world pictures based on attunement versus world pictures that sever the connection between understanding and attunement. MacIntyre himself presents a possibility for resolving such conflicts in case one tradition continually fails in its attempts to address certain key problems or issues. If another tradition has the conceptual resources to explain why it is that the first tradition continues to fail, then advocates of that first tradition may have to acknowledge its limitations and even transfer their allegiances. Whether that is the case for conflicts over attunement is not obvious (See Wong, 1989).

Moving to the end opposite from various forms of incommensurability, we find views holding that there must be substantial agreeement between traditions. The argument stems from a conception of the way interpretation works. We proceed on the assumption that the others we are interpreting live in the same world as we do.We subvert this assumption, however, if we attribute to them beliefs that substantially differ from our own. As Donald Davidson (1980) has argued, a belief is identified by its location in a pattern of beliefs, and it is this pattern that determines the subject matter of the belief, what the belief is about. If we attribute to others a pattern of beliefs that are different from our own, i.e., false beliefs, this tends to undermine the identification of the subject matter; to undermine, therefore, the validity of the belief as being about that subject. David Cooper (1978) applies a Davidsonian principle of charity to the question of whether different cultures have more or less the same morality. We can only identify others' beliefs as moral beliefs about a given subject matter if there is a massive degree of agreement between their and our beliefs about that subject matter. For Cooper this implies that the moral beliefs we attribute to others must be about something connected with welfare, happiness, suffering, security, and the good life. Michele Moody-Adams (1997) gives a more recent version of the same argument, starting with the premise that understanding others requires that there be quite substantial agreement about many of the basic concepts that are relevant to moral reflection. She concludes that “ultimate” or fundamental” moral disagreement is not possible.

The way that an earlier example of putative radical difference can be questioned serves as some confirmation of this argument from charity for strong agreement between traditions. Confucian conceptions of the state as family writ large are not especially puzzling even when we do not subscribe to them. We find similar themes that have arisen within the Western tradition, and again, it is possible to conceive what the appeal would be. However, these points also raise certain doubts about the use of charity to argue for strong agreement. . The fact that we can point to similar beliefs within our own tradition and that we can imagine what the appeal would lie behind such beliefs does not mean that we share those beliefs with others even as we attribute to them. It may be replied that the principle of charity does not require complete agreement, but only "substantial" agreement or agreement on "ultimate" or "fundamental" disagreement. A further question that will pressed against this position is how much agreement is sufficient for identification of others' beliefs as being about the same subject matter as ours. We do attribute to others error and simple difference (without judging that someone is in error) of belief about the same subject matter. We can attribute error to others if we believe them to be in circumstances that encourage error, and we identify such types of circumstance from past experience of discovering ourselves to be in error. Furthermore, we attribute simple difference of belief when we recognize that there is a range of reasonable interpretations or weightings to be given to evidence. Henry Richardson (1997) has argued that the principle of charity itself needs interpretation and hence cannot be the ultimate standard for interpretation. Interpreting a a philosophical text, requires taking account of the cognitive aims the authors had in writing what they did. Is it more charitable, Richardson asks, for a translator of Machiavelli's *The Prince* to resolve ambiguities and seek to maximize agreement between Machiavelli and ourselves? Or is it more charitable to set him out as intentionally provocative and deliberately cryptic?

An alternative to both the radical incommensurability and strong agreement positions is that there is no general answer on how much agreement or disagreement is to be found between complex and hetereogeneous traditions such as the Chinese and Western. As emerged above, one must distinguish between meaning and evaluational incommensurabilities. Furthermore, how much disagreement we will find not only depends on the particular subject matter but also on the answers we find most plausible within a larger context of inquiry: the attempt to explain others, their actions, practices, institutitions, and history. In such a larger context, attribution to others of beliefs different from ours may be more or less reasonable depending on how it fits into a reasonable explanation of them. And what counts as a reasonable explanation in particular cases will be set within the context of one's larger theories about persons and societies, among other things. One's explanation of people can reasonably attribute error or simple difference of belief on an indefinite number of important matters that might even deserve to be called ’fundamental’ as long as it seems plausible to attribute error of simple difference of belief to them in their epistemic situation as we construe it (see also Grandy, 1973). Or one's explanation can reasonably imply convergence of similarity of belief. An intermediate possibility is that the difference or similarity becomes more prominent as one defines the subject matter in a ‘thicker’ or ‘thinner’ way. Does the Chinese tradition recognize individual rights? The answer, as shall emerge below, may depend on how specifically one defines the notion of a right. If one defines a right rather thinly as what one has whenever one has justifiable claims on others to assure one's possession of things or one's exercise of certain capacities, then one can plausibly argue that there is a common notion of rights between the Chinese and Western traditions. If, on the other hand, one includes within one's definition of rights the idea that they

justifiable independently of what is a good and worthwhile life for human beings, then one plausibly argue against a common notion of rights.

2. Metaphysical and Epistemology Commensurability

One common portrait of the difference between the Chinese and Western traditions posits a radical incommensurability on the very nature of philosophical inquiry. Chinese philosophy is "wisdom" literature, composed primarily of stories and sayings designed to move the audience to adopt a way of life or to confirm its adoption of that way of life. Western philosophy is systematic argumentation and theory. Is there such a difference? One reason to think so is the fairly widespread wariness in Chinese philosophy of a discursive rationality that operates by deduction of conclusions about the particular from high-level generalizations. The seventeenth chapter of the *Zhuangzi* notes that the sage-king Yao looked for a suitable successor, found the perfect candidate in Shun, and then abdicated so that Shun could take over the throne. The result was glorious. However, when Kuai imitated Yao the result was disastrous. Tang and Wu were kings who fought and conquered. But Duke Bo also acted on that rule, fought, and lost. That is why it is impossible to establish “any constant rule.” Inspired by the achievement of insight or wisdom in some particular cases, we create general rules that we believe will work for many other cases in the future. The unfortunate result is that our original insights and wisdom are magnified beyond the scope of their applicability. Confucians are more willing to articulate their teachings in the form of principles, but such principles seem to function as designators of values or general considerations that ought to be given weight in judgments about what to do. Never lost is recognition of the necessity for the exercise of discretion in judgment according to the particular circumstances at hand. The best rules lose applicability in unusual circumstances. Rules and values conflict in many circumstances, and there are no "super-principles" to supply ready answers. The appropriate resolution to each conflict depends very much on the situation. In *Mencius* 7A35, Mencius is asked what the legendary sage-king Shun would have done if his father had killed a man.Mencius replies that the only thing to do would be to apprehend him. Shun could not interfere with the judge, who was acting on the law. However, Mencius continues, Shun would then have abdicated and fled with his father to the seacoast. As Mencius portrays it, then, Shun's actions strike a balance between the different values in tension with one another. The refusal to interfere with the judge is a way of acknowledging the necessity of impartially administering a social order. At the same time, fleeing with one's father is honoring the value of greater loyalty to family. Shun manages to honor both values at different moments in his dealing with the situation. Deduction from a principle could not yield such a balance. We are expected, however, to learn from stories such as Shun's, precisely because they function as concrete paradigms for judgment-making in the future. When we encounter situations that pose similar-looking conflicts between impartial concern and familial loyalties, we have Shun's judgment as a resource and a model. That model is not the same as a general principle that would deductively yield a judgment about what to do in the present situation. We must exercise judgment in determining whether new situations are similar enough to the case of Shun, and we must exercise judgment as to what actions would be parallel to Shun's actions.

Naes and Hanay (1972) have characterized Chinese philosophy as "invitational" in its method of

persuasion, meaning that it portrays a way of life in a vivid fashion so as to invite the audience to consider its adoption. The *Analects*, for example, portrays the ideal of the *junzi* (often translated as "gentleman" but perhaps more accurately glossed as the noble person) as realized by persons of genuine substance who are undisturbed by the failure of others to recognize their merits (1.1: "To be undisturbed by others yet not complain, is this not the mark of the *junzi*?"). In the *Mencius* (2A2), such a person possesses a kind of equanimity or heart that is unperturbed by the prospects of fame and success. This unperturbed heart corresponds to the cultivation of one's *qi* (vital energies) by uprightness. One might be able to see such passages as appealing to experiences the audience might have in its encounters with persons who do seem to possess special strength, substance, and tranquillity through identification with and commitment to a cause they perceive to be far greater than themselves. One need not interpret such sayings as attempting to persuade by the pure emotive effect of certain words, as in propaganda. Rather, they may correspond to a way of doing philosophy that attempts to say something about values in life that can be supported by experience, even if not all testimony will agree (Kupperman, 1999). The Daoists recommend a way of life that they explicitly characterize as one that cannot be argued for, but their recommendation receives some support through commonly shared experience. Consider again the notion of *wuwei* and its illustrations in the *Zhuangzi* through stories of exemplary craft. Most famously, Zhungzi's Cook Ding cuts up an oxen so smoothly and effortlessly that his knife never dulls, and it is if he is doing a dance with his knife as it zips through the spaces between the joints. He does this not through "perception and understanding" but through the *qi*, the vital energies of the body. His marvelous skill is knowledge of how to adjust his own movements to the spaces within oxen that he and the oxen form seamless wholes. Similarly, Woodcarver Qing has learned to prepare for carving his marvelous bellstands in such a way that he clears his mind of all distraction and sees the stand within the timber he has selected. Suggested here is a portrait of acting in the world that consists of complete and full attention to present circumstances so that the agent can act with the grain of things (the Cook Ding passage refers to *tianli* or heavenly patterns). Such a portrait does resonate with the actual experience of craftspeople, artists, athletes, musicians and dancers who have advanced beyond self-conscious technique and rule-following, who become fully absorbed in the experience of working with the material, the instruments or in the movement of their bodies, and who experience their actions as an effortless flow and in fact perform at very high levels. In such ways, Chinese thinkers draw a picture of the world that must in the end by evaluated by explanatory power in some very broad sense. We must ask whether the picture helps make sense of our experience of the world (again in a broad sense of ‘experience’ not limited to quantifiable observations in replicable experiments) and whether it preserves features of that experience that think are *prima facie* genuine.

So then, is it right to say that Chinese philosophy is invitational while Western philosophy is argumentative? One answer is that there is a difference but that it is more a matter of degree than an absolute contrast. It was Aristotle, after all, who said that discussions about the good in human life cannot be properly assimilated by the young because they do not have enough experience of life (*Nichomachean Ethics* I.3). And Plato despite his insistence on the centrality of argumentation to philosophy, dispatches the short analytical arguments presented in Book I of the *Republic* in favor of lengthy expository portraits of the ideal city-state and the harmonious soul for the rest of that work. Those portraits sometimes present only the thinnest of arguments for crucial premises, and at other times no argument at all. Some of his claims, about the divisive effects of family loyalties and the ill-effects of democracy, obviously appeal to experience, even if not all testimony will agree. In fact, it is hard work to find an acknowledged great in

the Western tradition to whom such characterizations do *not* apply, at least to some degree. Sometimes, as in Spinoza (*The Ethics*), the contrast is glaring between the aspiration to prove points by way of deductive argument from self-evident axioms and the obvious source of those points from experience of life. It is true that much Western philosophy, especially of the late modern variety, and most especially emanating from the United Kingdom and North America, attempts to establish its claims through argumentation that is more rigorous than appeals to experience and explanatory power in the broad sense. But it must also be noted that there is argument in Chinese philosophy. Chad Hansen (1992) has pointed out the pivotal role of the philosopher Mozi, who criticized the Confucians for an uncritical acceptance of tradition and who explicitly introduced standards for the evaluations of belief. This introduction of argumentation required response in kind. Mencius gives a Confucian response to to the Mohists and argues on behalf of his theory of human nature as containing the germs or sprouts of the ethical virtues, in the form of natural dispositions to have certain kinds of feeling and judging reactions to situations, such as compassion for a child about to fall into a well (2A6, and see Shun, 1997 for an extensive analysis of argumentation in the *Mencius* text). He defends himself against the arguments of rival theorists who hold that human nature has no innate ethical predispositions but is neutral (6A). Xunzi, a later Confucian thinker, attempts to give a refutation of Mencius's theory in favor of his own theory that human nature has dispositions that get us into trouble and that ethical norms are an invention designed to avoid that trouble (*Xunzi*, chapter 23). Methods of argumentation reach their most sophisticated state of development in Xunzi (See Cua, 1985).

Differences in the way philosophy is conceived may reflect differences in the interests philosophy is meant to satisfy. Chad Hansen (1992) points to another possible difference in interests -- this time in interests that language is meant to satisfy, arguing that the classical Chinese thinkers did not conceive of the primary function of language to be descriptive and as attempting to match propositions with states of affairs, but rather as a pragmatic instrument for guiding behavior. In fact, Hansen sees the Chinese tradition as centrally concerned with the conflict of *daos*, which he defines as sets of behavior-guiding practices, including discourses. Western interpreters have been unable to see this, argues Hansen, because they have imposed their own concerns with correspondence truth and metaphysics on the Chinese tradition. They have as a result imposed upon Daoism an irrational mysticism focused on a metaphysically absolute *Dao*. Michael LaFargue (1992) also argues that the *Daodejing* is not to be interpreted as as concerning some metaphysical entity called the *Dao*, but is rather concerned with self cultivation that allows one to have a transforming experience of deep and peaceful stillness within one's personal center. *Wuwei* is the style of action that is rooted in such an experience. David Hall and Roger Ames (1987) give a related interpretation of Confucius, in part reacting against Herbert Fingarette's (1972) influential interpretation of Confucius' *Dao* as an ideal normative order transcending the contingencies of time, place, history, and culture. Hall and Ames argue Confucius's *Dao* was not conceived as a tradition and language-independent reality against which linguistically formulated beliefs were to be measured as reliable or unreliable, but in fact a cumulative creation of individuals working from within a context provided by a society's tradition, consisting of customs, conventions, conceptions of proper behavior and good manners, conceptions of right conduct and of what is of ultimate value and of what lives are worth living.

These interpretations perform valuable functions in questioning what is sometimes an unreflective imposition of Western philosophical agendas on Chinese thinkers. The debate will go on, however.

Concerning Confucius, it is true that the *Analects* often displays an attitude of tolerance and flexibility in judging where the *Dao* lies. On the other side, it can be pointed out that in sayings such as 1.2 (filial piety and brotherly love are at the root of the virtue of *ren* or humanity), there is no indication that the claim is limited to Chinese culture but extended to human beings generally. One way to understand it is to take it as saying that human beings have to learn to respond to a kind of authority that is not based on force and coercion, but respect and care. Or consider the consistent Confucian theme that rulers cannot hold power simply on the basis of law and punishment. There is no sign such judgments are meant to be limited in scope to one's own time and place. Concerning the *Daodejing*, it is clear that there are very strong practical concerns underlying the text. A way of life is being recommended (as in Hansen), and perhaps that way of life is rooted in a certain kind of transforming experience (as in LaFargue). On the other side, it could be argued that such practical and experiential concerns do not exclude metaphysical concerns. Consider chapter four of that text where *Dao* is described as being empty, as seeming something like the ancestor of the myriad of things, as appearing to precede the Lord (*di)*. For something that at least *looks* metaphysical in the *Mencius,* consider aforementioned 2A2, concerning the unperturbed heart that can be achieved by cultivating one's floodlike *qi.* Such *qi* is vast and unyielding, and if cultivated with uprightness will fill up the space between *tian* (Heaven) and earth. Perhaps the lesson to draw is not that Chinese thinkers lacked metaphysical concerns but that they did not separate practical from metaphysical concerns in the way that contemporary Western thinkers might.

However this issue is resolved with respect to the classical Chinese thinkers, few have disputed that classical concepts such as that of nonbeing *eventually* acquired frankly metaphysical meanings in the Chinese tradition, where it refers at the least to an indeterminate ground in which the determinate “ten thousand things” are incipient (Neville, 1989). This embrace of an indeterminate ground of the determinate may reflect the decision to give the phenomenon of change a fundamental place in ontology, rather than an absolutely stable being as in Parmenidean ontology and as later reflected in Aristotelian and Cartesian notions of substance (Cheng, 1989, 1991). The revival of interest in Chinese metaphysics has partly been fueled by the perception that twentieth century physics has in fact undermined the strategy of giving determinate being ontological primacy (Zukov, 1979). The Neo-Confucian Chu Hsi (*Zhuzi yulei)* reinterpreted ethical themes inherited from the classical thinkers and grounded them in a cosmology and metaphysics. On his conception of *ren* as an all inclusive virtue, it constitutes the *Dao* and consists of the fact that the mind of Heaven and Earth to produce things is present in everything, including the mind of human beings. Another great Neo-Confucian, Wang Yang-Ming (*Quan xilu)* does seem more pragmatic than metaphysical, He taught of the sage who formed one body with Heaven and Earth and the myriad things, but he showed little of Chu's interest in the *li* or principle of existent things. The investigation of things prescribed in the *Great Learning* (*Da Xue*) was not the empirical inquiry Chu envisioned but a rectification of the mind with evil thoughts. Perhaps Chu and Wang represent development of tendencies that were present from the beginning, and between which there was never conceived to be a mutually exclusive choice.

When we get to Chinese Buddhism, there is more evidence for metaphysical concerns that at the same time are urgently practical. It is difficult to view as anything but a metaphysical doctrine the Buddha's view of the self as a floating collection of various psychophysical reactions and responses with no fixed center or unchanging ego entity. He did not deny that we think of the self as a fixed and unchanging

center, but considered such a self a delusion. Our bodily attributes, various feelings, perceptions, ideas, wishes, dreams, and in general a consciousness of the world display a constant interplay and interconnection that leads us to the belief that there is some definite ‘I’ that underlies and is independent of the ever-shifting series. But there is only the interacting and interconnected series. This metaphysical concern, of course, had deep practical implications for the Buddha. It points toward the answer to human suffering, which ultimately stems from a concern for the existence and pleasures and pains of the kind of self that never existed in the first place. The recognition that none of the "things" of ordinary life are fixed and separate entities, anymore than the self is, leads to a recognition of all of life as an interdependent whole and to the practical attitude of compassion for all of life. In a comparative perspective, one cannot help but be struck by the similarity between the Buddhist view of the self and David Hume's doubts about the existence of a unitary and stable self (*Treatise of Human Nature*, 1.4.6). Consider also Derek Parfit's (1984) point that acceptance of a Humean or a Buddhist view of the self can lead to sense that one is less separate from other selves and to a wider concern when "my" projects seem not so absolutely different from "your" projects. However one might regard the argument for impersonal concern from such a view of the self, the view itself may seem to have a claim to a our renewed attention. It certainly fits better with a naturalized conception of human beings as part of this world and not as Cartesian thinking substances that somehow operate apart from the rest of nature.

3. Ethical Commensurability

Confucianism is a perfectionist virtue ethic if such an ethic is distinguished by its central focus on three subjects: character traits identified as the virtues; the good and worthwhile life; and particularist modes of ethical reasoning. These three subjects are interrelated. The virtues are traits of character necessary for living a good life. The virtues typically involve acting on particularist modes of ethical reasoning that do not rely on deducing specific action-guiding conclusions about how to act from general principles but rather on judging in the context at hand what needs to be done. Consider some of the virtues that belong to the *junzi* (the noble person): *ren* (humanity, benevolence), *xiao* (filial piety), *yi* (righteousness), and *li* (acting according to ceremonial ritual or more generally propriety). The very concept of y*i* connotes the ability to identify and perform the action that is appropriate to the particular context (*Analects* 4:10 says that the *junzi* is not predisposed to be for or against anything, but rather goes with what is *yi*). While traditional rules of ritual provide one with a sense of what is courteous and respectful action given standard contexts, the virtue of *yi* allows one to identify when those rules need to be set aside in exigent circumstances (see Cua, 1997). The previously discussed example in the *Mencius* of Shun and his father shows how a ruler's more general concern for his subjects and his filial duties to his fathers must be balanced in ways that cannot be given by principle but only by reflection on what the particular circumstances suggest and allow. Finally, consider that another example from the Mencius about the time when Shun wanted to marry. He knew that his parents, not the wisest nor the best of parents, would not permit him to marry if told of Shun's intention. Shun went ahead and got married without telling his parents, an act that normally would be a grave offense against filial piety. Two reasons are given for the justifiability of this act. One is that the worst way of being a bad son is to provide no heir (4A26); the other is that letting his parents thwart his desire to realize the greatest of human relationships which in turn would cause bitterness toward his parents (5A2). Hence an act that normally would be a grave

offense against filial piety constitutes filial piety in the particular circumstances. Particularist modes of reasoning are needed, then, to judge when the usual rules apply, to balance conflicting values, and to specify the concrete meaning of single values in application to context.

The parallels to ancient Greek virtue ethics, medieval virtue ethics, and also to contemporary virtue ethics in the West are striking, and help to account for the renewal of Western interest in Confucianism. Eastern and Western virtue ethics converge in focusing on certain virtues as crucial for ethical development of the person. There are particularly interesting discussions of courage and the possible role of fear in Mencius and Aristotle (see Van Norden, 1997). Particularist modes of reasoning in Confucianism parallel the Aristotelian notion of a *phronesis* or practical wisdom that depends significantly on knowledge of particulars acquired through experience. A good example is his doctrine of the mean, which holds that virtuous action and feeling consists of avoiding the extremes of deficit and excess. The doctrine does not imply that we ought always to act moderately and with moderate feeling. Aristotle says that the mean is “relative to us,” giving the illustrative analogy that too little food for Milo is too much for the beginner in athletic exercises (*Nichomachean Ethics*, 2.6). Depending on the situation, the appropriate action and feeling may be extreme on a common sense understanding but appropriate given the agent and the circumstances. Part of the contemporary revival of virtue ethics is premised partly on a reaction against the ambition of modern ethical theory to guide primarily through general principles of action rather than through the specification of ideal character traits. Virtue ethics also tend to embody the theme that the ethical life of right (and in the case of Chinese and contemporary Western virtue ethics) caring relationship to others is necessary for human flourishing. In the *Mencius* this theme emerges in identification of the distinctively human potentials with the incipient tendencies to develop the moral virtues (*Mencius* 2A6, 6A1, 6A3, 6A7). Aristotle held that reason makes us distinctively human and that our reason and social nature compel recognition of the desirability of the ethical life for human beings (see Nivison, 1996 for comparisons of Aristotle and Mencius; and Yearley, 1990 for comparisons of Acquinas and Mencius). Xunzi is equally emphatic about the necessity of right and caring relationship to others for human flourishing, even though he denies (at least when he is criticizing Mencius) that human nature contains tendencies to engage in such relationships (see Ivanhoe, 1991, on the way ethical norms help human beings to flourish; and Nivison, 1996a, 1996b, Van Norden, 1992, Wong, 1996b, and Kline, 2000, on the difference between Mencius and Xunzi's theories of human nature; see Goldin, 1999, for a book-length treatment of Xunzi's philosophy).

The similarities coexist with significant differences, however. There is no parallel in Greek virtue ethics for the centrality of family life in the Confucian conception of the good life. Part of the reason for this lies in the Confucian appreciation for the family as the first arena in which care, respect, and deference to legitimate authority is learned (*Analects* 1.2). The way in which particularist reasoning is illustrated in historical stories such as those about Shun is also a distinctive feature of Confucian ethics. These stories present paradigms of good judgment and of good individuals, from which persons engaged in ethical cultivation of themselves should learn. Another distinctive feature of Confucian ethics is the emphasis it gives to an aesthetic dimension of the good life. To act according to ritual propriety is not simply to conform to notions of appropriate behavior in this or that context. It is to act with the right attitude, reverence, say, in the case of serving one's parents in an appropriately respectful manner, and tt is to express such an attitude so gracefully and without internal conflict that doing so has become second

nature (see Kupperman, 1999 and Cua, 1997). The importance attached to *li*, to ritual propriety itself, indicates the Confucian appreciation for the role of culture and convention in enabling human beings to express ethical attitudes toward each another such as care and respect. It is not as if bowing naturally *means* deferential respect; it must be agreed through convention that it does mean something like this (see Fingarette, 1972; see Shun, 1993, for a discussion of the relationship of *li* to the important virtue of *ren*). Mencius and Xunzi engaged in a vigorous, provocative debate over human nature and whether there are natural tendencies that form the basis for development of a good person. They debate in a highly sophisticated manner issues as to whether ethical norms and values are discovered or invented are debated, and their arguments are based partly on what would make for a plausible explanation of how human beings develop into goodness and of how they become bad. Taking all these distinctive features together, it is fair to say that Confucianism offers an especially rich moral psychology (see Nivison, 1996, for several influential essays on moral psychology in comparative perspective, including "Motivation and Moral Action in Mencius," "Philosophical Voluntarism in Fourth-Century China," "Two Roots or One?" and "Xunzi on 'Human Nature'").

One debate that arises within the comparative perspective, however, is whether the Confucians had anything that fits the Western notion of morality. The words 'ethics' and 'ethical' have been used to in this piece to remain neutral on this matter. Some contemporary thinkers (most prominently, Williams, 1985) have tended to confine the 'moral' to a relatively narrow set of characteristics associated with Kant's moral philosophy -- a belief in universal laws validated by pure reason, a belief that responsibility for one's actions requires a freedom from determination from external causes -- and on this view of the moral, it could be argued that there is no equivalent in Chinese philosophy (see Rosemont, 1988). If such a contrast is made, then Confucians are acknowledged to have an ethics as opposed to a morality, where an ethics does embrace questions about value, how one ought to live one's life, and what the good life consists in. One question to be debated here is whether Western notions of the moral are so uniform and narrow as to conform to one philosopher's (even a great one) specific conception of the moral. On the criteria given by Williams, Hume wouldn't have a morality, even though he used the term. It is true that a dominant strain of modern Western morality makes use of a crucial distinction between a morally significant sphere of life that has to do primarily with one's relationships with others and a "private" sphere of life in which one has moral "time-off" that is no one's business but one's own. If it is essential to one's conception of the moral that it be set off from such a private sphere in which moral judgments supposedly have no application, then Confucians would have no morality. Here again, however, it has to be asked whether this is too narrowing. It would eliminate certain utilitarians, for example, who insist that there is no purely private sphere because any type of action or omission could have substantial impact on others given the right circumstances.

Another potential contrast arises from the focus in modern Western moralities on individual rights to liberty and to other goods, where the basis for attributing such rights to persons lies in a moral worth attributed to each individual independently of what conduces to individual's responsibilities to self and others. Confucianism lacks a comparable concept, given its assumption that the ethical life of responsibility to others and individual flourishing are inextricably intertwined. A frequently-made criticism from the Western side is that Confucianism fails to provide adequate protection to those legitimate interests an individual has that may conflict with community interests. On the other side, some

advocates of Confucian ethics criticize rights-focused moralities for ignoring the social nature of human beings and of portraying human life in an excessively "atomistic" or "individualist" conception of persons (e.g., Rosemont, 1986). Against those who argue that Confucianism does not protect the individual enough, it could be replied that the Confucian framework of responsibilities to others can afford significant protections to the individual and arguably addresses the human need for community and belonging better than rights frameworks (Rosemont, 1991). Moreover, it is possible that rights in some sense can play a role in the Confucian tradition, even if such rights are not grounded in the idea of the independent moral worth of the autonomous individual. Within that tradition, rights may be seen as necessary for protecting individuals' interests when the right relationships of care irretrievably break down (Chan, 1999). Rights in the sense of justified claims to be protected in one's speech even when protest and dissenting against authority can be justified as conducive to the health of the community. Mencius recognized a right to revolution against tyrannical kings (1B8); he furthermore advised kings to attach more weight to the opinions of his people than to those of his ministers and officers in making certain crucial decisions (1B7). Xunzi recognized the need for subordinates to speak their views freely to their superiors (*Xunzi*, *Zigong*, *Way of the Son*). If we carry the reasoning in Mencius and Xunzi one step further, we see the need to protect a space in which they may speak freely without fear of suppression, and hence a derive a right in the "thin" sense of what one has whenever one has justifiable claims on others to assure one's possession of things or one's exercise of certain capacities. On the other side, one must be wary of oversimplifications of Western rights-oriented ethical codes. The social nature of persons is not denied by all such codes (of the major theories only Hobbes seems to take an unambiguously “atomistic” view of human beings, and Rousseau and Locke seem to require no such view).

The fact that there are developments of each tradition that bring each closer to the other may suggest that each could learn from the other. Even if not all rights-oriented codes are "atomistic," an increasing worry about Western culture as it has actually developed in practice is the prevalence of an individualism that Tocqueville defined as a "calm and considered feeling which disposes each citizen to isolate himself from the mass of his fellows and withdraw into the circle of family and friends," such that "with this little society formed to his taste he gladly leaves the greater society to look after itself." Such people, Tocqueville observed, form "the habit of thinking of themselves in isolation and imagine that their whole destiny is in their hands." They come to "forget their ancestors" and also their descendants, as well as isolating themselves from their contemporaries. "Each man is forever thrown back on himself alone, and there is danger that he may be shut up in the solitude of his own heart" (1969, pp. 506, 508). Those impressed with this worry and connect it with gross inequality in the most affluent nation in the world would do well to look to a tradition that appreciates the way we thrive or falter within specific communities that nurture or shut us out. On the other side, a tradition that has tended to value the idea of social harmony at the cost of sufficiently protecting dissenters who desire to point out abuses of power or just plain bad thinking by authorities would do well to look at another tradition that does not value social harmony as highly but has endured and is vigorous.

These arguments for greater compatibility between Chinese and Western ethics do not eliminate all significant differences between them on the subject of rights. It is possible to argue that even if responsibility-frameworks are developed and institutionalized to provide genuine protection to dissenting individuals, they cannot provide as much protection as rights frameworks when individual interests

seriously threaten communal or social interests. And if Western ethics sometimes provides more protection to the individual against communal or social interests, this could be seen as unacceptable from a Confucian standpoint. One possible stance on these kinds of differences is evaluational incommensurability. The stance is that each tradition is not wrong to emphasize different values, that no judgment of superiority can be made here. The argument for this may start with the claim that each sort of ethic focuses on a good that may reasonably occupy the center of an ethical ideal for human life. On the one hand, there is the good of belonging to and contributing to a community; on the other, there is the good of respect for the individual apart from any potential contribution to community. It would be surprising, the argument goes, if there were just one justifiable way of setting a priority with respect to the two goods, even when we take into account the justifiable ways in which the two kinds of ethics could be brought closer together. On this view, comparative ethics teaches us about the diversity and richness of what human beings may reasonably prize, and about the impossibility of reconciling all they prize in just a single ethical ideal (e.g., Wong, 1984, 1996).

Daoist ethics are often cited as exemplars of radical difference with the Western tradition. A lot of the case for radical difference rests on the strong skepticism in these ethics about the benefits of conceptualized distinctions between good and bad, right and wrong. Yet these ethics make recommendations that add up to putting forward a way of life. In the *Zhuangzi*, that way of life involves not taking taking oneself and one's ideas so seriously. Chapter two contains a story of monkeys who were furious with their keeper when he announced the policy of three nuts every morning and four in the evening. The keeper then announced a change: "four nuts in the morning and three in the evening," this time to the great delight of the monkeys. Kupperman (1999) suggests that we are invited to view our own urgent concerns in the humorous light of the monkeys' concern about the difference between the two policies. At the same time we are invited to question our own judgment of the monkeys. Why think the monkeys are silly if our urgent concerns might look to some other kind of creature the way the monkeys' concerns look to us? The way of life recommended in the *Zhuangzi*, then, includes openness to what might escape our current conceptualizations and preconceptions. We are invited to see that our conceptualizations of the world are inevitably incomplete and distorting. We attempt to order the world by sorting its features under pairs of opposites, but opposites in the real world never match up neatly with our conceptual opposites. Real "opposites" escape our attempts to cleanly separate them. Despite our best efforts, they switch places in our conceptual maps, blur, and merge into one another. That is why chapter two of the *Zhuangzi* says that the sage recognizes a "this," but a "this" which is also "that," a "that" which is also "this."The appropriate response to the inadequacies of our conceptual structures is to remain open to what those structures distort or hide. In chapter five, men who have had their feet amputated as criminal punishment are scorned by society, but not by their Daoist masters, who see what is of *worth* in them. In chapter one, Zhuangzi chastises his friend Huizi for failing to see beyond the ordinary, humdrum uses of some large gourds. Huizi tried using one of the gourds for a water container, but it was so heavy he couldn't lift it. He then tried to make dippers from them, but they were too large and unwieldy. He deemed the gourds of no use and smashed them to pieces. Zhuangzi asks why he didn't think of making the gourd into a great tub so he could go floating around the rivers and lakes, instead of worrying because it was too big and unwieldy to dip into things! "Obviously you still have a lot of underbrush in your head!" concluded Zhuangzi. He does not deny that the more ordinary uses are genuine uses for the gourds, and indeed, they are. Rather, Zhuangzi's point is to clear the underbrush from our heads and to get

an *enlarged* view of what is of value.

Much of the value of Daoist ethics lies in its warnings against the constricting effects of conventional ethical codes, the blinkering of vision that comes with what we might otherwise regard as admirable integrity and dedication. The other side of this warning is an intriguing positive: that there is a way we can pay attention to the world that allows us to "see around" our blinkering conceptualizations, to see what is of value that we have missed, to move with the grain of things. It is not easy to find an analogue to someone such as Zhuangzi in the Western tradition. There are some important parallels in the Hellenistic Stoics and Epicureans to certain themes in Zhuangzi. They, like him, emphasized the need to accept the inevitable in human life, the need to dampen one's desires to achieve tranquillity in the face of the inevitable, and to identify with the world that makes acceptance and dampening of desires possible (Nussbaum, 1994). On the other hand, there is contrast in the Stoic belief in *logos* as the basis of order in the universe. There are parallels to some Zhuangist themes in Nietzsche: the skepticism about the adequacy of our conceptualizations of the world and of value; the warnings against conventional moralities as constricting, and the awareness of how the application of ethical judgment to others can be a means of asserting power over them (*The Genealogy of Morals*). However, Zhuangzi's vision possesses a generosity and inclusiveness, an embrace of the lowly and cast-off, that seems anathema to Nietzsche's celebration of the übermensch and his project of fashioning himself like a work of art. Nietzsche proposes strong, vital desire at the heart of this aesthetic project, rather than the dampening of desire. He represents a kind of radical individualism that did not find a congenial home in the Chinese tradition (Solomon, 1995).

In Buddhism, especially Chan Buddhism, there also is rejection of conventional ethical values as blinkering and distorting (see Hui Neng, *Liuxu tanjing*, and The *Recorded Conversations of I-Hsüan*), and also a sense that one can become attuned to the world so as to move with its grain. This is not surprising since Buddhism was profoundly influenced by Daoism upon its importation into China. However, Buddhism may have especially challenging implications for Western ethics in its special emphasis on the elimination of suffering and on the way it explains suffering by referring to the human attachment to self as fixed ego entity. As noted above in discussing Parfit's connection to the Buddhist view of the self, realization that the self is not a bounded and discrete entity may encourage a much more impersonal view of oneself and one's projects and desires. One's concern widens to all of life, and one dampens one's desires so as to lessen attachment to the self's cares and concerns. Some may find this an unacceptably demanding ethic. It may seem to drain all passion from life, and it requires that we dampen the attachment we have not only to our selves but also to special others. This negative reaction may fit with Kupperman's (1999) characterization of much Western ethics as upholding only a limited altruism that allows one a private sphere of life free from moral demands and in which one gives much more weight to the cares and concerns of the self and those close to the self. However, as the above comparison with Parfit suggests, there are themes in Western philosophy that parallel the kind of impersonal altruism urged upon us by Buddhism. Some utilitarians have strongly held to the theme that each counts for one in calculating what produces the greatest good, and they have derived challenging consequences from that theme for the question of what one should be prepared to give to alleviate the suffering of strangers (see Singer, 1972, and Unger, 1996), arguing that the way many in affluent nations indulge themselves and their own is simply insupportable in a world of widespread and severe suffering. Some have seen the sort of

impersonal concern that utilitarianism may demand as an indication that it unsuitable for human beings, who are so strongly partial to themselves and their own (see Williams, 1981 and Wolf, 1982). Buddhism presses for the possibility that impersonal concern is humanly possible, and the fact that it is a vibrant and long-lived tradition with many committed practitioners provides some support for the viability of impersonal concern as a ideal that is capable of claiming allegiance and influencing how people try to live their lives (see Flanagan, for a reference to Buddhism in support of the viability of such an ideal .

4. Why Do Comparative Philosophy If It's So Hard?

The most obvious sin of doing comparative philosophy is assimilating another tradition to one's own by unreflectively importing assumptions, frameworks, and agendas into one's reading of that other tradition. Sometimes too much charity (as a principle of interpretation) is insufficiently respectful of the distinctness of the other tradition. There are more subtle dangers. If one is a dissident from main trends in one's home tradition, one is tempted to find another tradition that "got it right." This is fine as long as the desire to find another such tradition does not lead to distortion or oversimplification of that other tradition. These are dangers one can recognize but not always avoid successfully, because success may require knowing a lot about the other tradition when it is hard enough to master a single tradition to the point where one can avoid saying silly things about it. Are the risks worth it?

One reason for thinking so is that comparative philosophy is an instance of a sound and sensible strategy for doing philosophy. When facing hard problems it is simply a good strategy to consider a wide range of enduring, respected ideas bearing on those problems. We of course must be wary of the possibility that the other tradition is not really addressing the same problem we are, or that it is addressing only part of the problem we are addressing. But when there is common address of a problem, it is not always the case that one tradition must be adjudicated as entirely right and the other as entirely wrong. There is a good possibility that each tradition has something insightful to say about some aspect of the problem and that each tradition could incorporate something of what the other tradition has to say (see Yu and Bunnin, 2001). When one crosses traditions in enacting this strategy, there is the opportunity for fruitful interaction and mutual influence. Already discussed above is the opportunity for fruitful interaction between rights-oriented traditions and traditions such as Confucianism focused on the value of relationship and community. Consider another area of potential interaction: when a tradition as long-lived and as sophisticated as the Confucian tradition brims full with writing on the nature of agency, human motivation, and the problem of developing ethical excellence and commitment, one cannot afford to ignore it (see Ivanhoe, 2000, for portraits of the tradition of Confucian and neo-Confucian thinkers on these subjects). Confucianism and Daoism emphasize the need to to pay attention to the concrete details of the situation at hand and displays healthy skepticism about the power of general principle to reveal what sort of action is suitable to the situation. Confucianism displays an appreciation for the power of custom, convention and ceremony for helping to make vivid and concrete and meaningful such ethical abstractions as love, respect, and care. From these themes, there is much to be learned, especially if one's home tradition has had a strong focus for a good portion of the modern period on the top-down deduction of specific ethical judgments from extremely abstract principles. At the same time, an appreciation for the concrete and for the culturally specific may obscure the possibility of general and transcultural principles

that help to evaluate the concrete and culturally specific, and the Chinese tradition could benefit from interaction with the Western (Cua, 1985). Finally, recall the case of the Buddhist ideal of impersonal concern being brought to bear on a debate in Western philosophy over the viability of ideals of impersonal concern. This illustrates the point that comparative philosophy can stretch one's sense of possibility, in this case, of human possibility. That is a benefit in itself.

Robert Holkot [Holcot]

Robert Holkot, OP (d. 1349) belonged to the first generation of scholars to absorb and develop the views of William Ockham. He is particularly known for his "covenantal theology" and his views on human freedom within the framework of a divine command ethics. He developed an original theology grounded in Ockham's logic and metaphysics, and his works were influential into the sixteenth century.

1. Life and Work

Robert Holkot was from the village of Holcot (or "cot in the rock" as he glossed it) near Northampton, and apparently a commoner: he spoke of how the most capable men seemed to come from humbler backgrounds. He joined the Dominican order, and if he received the usual training, obtained his initial education in arts, logic, Aristotelian philosophy, and theology within the Dominican schools. He studied at Oxford, commenting on Peter Lombard's *Sentences* in the years 1331-1333. Once he obtained his doctorate in theology, he served as Dominican regent master there. Subsequently, Richard of Bury, the Bishop of Durham, chose Holkot as one of his clerks to work with him in London. Tradition also places Holkot at Cambridge, where he may have served as a Dominican lecturer or regent master in theology prior to 1343, when he is known to have returned to the Dominican priory of Northampton. He remained at Northampton, teaching and writing, until his death of the plague in 1349, acquired, as the story has it, while ministering to the sick.

Holkot produced a number of works over his lifetime. While he was at Oxford, he lectured on Peter

Lombard's *Sentences*, on Matthew and the Book of the Twelve Prophets, and engaged in ordinary and quodlibetal debates. He also engaged in a dispute with his fellow students about epistemology, published as the *Sex articuli*, and probably wrote another work, *De imputabilitate peccati* or *On the imputability of sin*. A text, *De stellis, On the stars*, a rough commentary on Aristotle's *De caelo* was probably originally intended as part of his commentary on the *Sentences*, but circulated as a separate tract. His *Sermo finalis*, the final sermon given at the time of passing on the lectureship on the *Sentences* to the next Dominican, also survives. While in London, Holkot helped Richard of Bury with the book, the *Philobiblon*. Two works for preachers, the *Moralitates* and the *Convertimini*, date from his later years. His most famous Biblical lectures, on the book of Wisdom, are associated with Cambridge, and survive as the *Postilla super librum Sapientiae*. Portions of lectures on Ecclesiastes also survive, most likely from his time in Northampton, and he was known to be giving lectures on Ecclesiasticus when he died. A sermon collection, spanning his career, has also been preserved. Most of these texts exist (if they have come down to us) only in manuscript or early sixteenth century editions. Modern editions are available, however, of selected portions, sermons and questions, and of the *Sex articuli*.

2. Relation to Ockham

2.1 Ockham's influence

Although Holkot was a Dominican, well versed in the texts of Aquinas, his philosophy and theology owe much more to the scholastics of the fourteenth century than to the thirteenth. William Ockham exercised the most important influence. The hallmarks of Ockham's philosophy are: his reduction of Aristotle's ten categories of being to substance and quality; his analysis of the other eight categories and many other terms of philosophical art as connotative terms, best understood as exponible into more fundamental absolute terms denoting substances and qualities; his rejection of Aristotle's final, formal and material causes as properly causal, keeping only efficient causality; his conception of mental language as a logical thought structure existing independently of spoken language; his reformulation of the prevailing views about reference (supposition theory) to accommodate his spare metaphysics; his rejection of species as necessary for knowledge in favor of intuitive cognition or the direct intellectual cognition of objects; and his view that the ethical precepts of the Ten Commandments are not absolute but subject to divine will, such that God could, without contradiction, have created a system in which moral good involves obeying the opposite of each of the traditional commands. Holkot assumed most of Ockham's philosophical positions as foundational, taking them for granted in the development of his theology.

Holkot was not much concerned with defending or exploring his Ockhamist philosophical presumptions. They appear as premises, scattered throughout his texts, rather than subjects of extended analysis.

2.2 Differences with Ockham on epistemology

Holkot did differ with Ockham in the details of his epistemology. Holkot, like Ockham, adopted the terms "intuitive" and "abstractive" cognition to designate the basic forms of human understanding. But

Holkot's treatment of intuitive cognition differed from Ockham's on the question of the possibility of intuitive cognition of non-existents. For Ockham, intuitive cognition was the direct intellectual cognition of the presence and existence of an object. Holkot used Ockham's own style of analysis to develop his critique. He noted that "intuitive cognition" was a connotative term, connoting both a kind of quality, which is cognition, and the cognized object as it exists and is present in itself. The term stands for the co-presence of cognition with its object. This led Holkot to argue against Ockham's contention that God's omnipotent power to cause directly whatever is ordinarily caused through secondary causes would enable God to conserve the intuitive cognition of an object even after the object has been destroyed. Holkot objected that given the meaning of the term "intuitive cognition," if God were to conserve cognition of an object after destroying it, that cognition by definition could no longer be an intuitive cognition. It would be an abstractive cognition, the kind of cognition present in the absence of an object.

Holkot also differed with Ockham about the nature of abstractive cognition. He argued in favor of retaining species as part of natural and cognitive processes. In *De stellis* he refers to the sun propagating the natural species of light through the medium of the air. He did not consider the species operative in cognition to be such natural species, however. The term ‘species’ when used to refer to the whiteness in one external object and to the whiteness in another could be called univocal, having the same meaning in each case, but the term ‘species’ used to refer to the whiteness in an object as a quality and to the whiteness representing the object in the intellect was equivocal. The intellectual species is only a likeness of the thing in the sense of representing it (like a statue of Hercules in relation to Hercules), and we experience it in ourselves as it enables us to think about an external object in the absence of that object. Holkot was not much concerned whether such "spiritual qualities" were called "species," "idols," "images," or "exemplars" as long as they were understood to serve as representatives of things or even "knowledge habits" and not as the natural qualities that exist in extramental reality. Holkot's opponent was not Ockham, here, however, but his Dominican contemporary William Crathorn, who had argued for the view that natural and cognitive species were the same in kind. Holkot ridiculed Crathorn's position at length in the *Sex articuli*, on the grounds that if Crathorn were right, our minds would become white or black, hot or cold, depending on what we were thinking about. Crathorn was arguing in line with a long tradition stretching back to Roger Bacon. Holkot's sharp disjunction between natural and spiritual "likenesses," natural and spiritual qualities, went beyond the traditional distinction between sensible and intelligible species and seems to show the effects of the Ockhamist critique, even while he retained remnants of the Aristotelian vocabulary.

3. Natural Theology

3.1 What reason cannot do

Ockham had argued for stringent limits on the ability of reason to establish the existence of God. While an argument for the existence of God as "first conserver" of things could be made, Ockham had argued against the ability of natural reason to prove there was only one divine being. Holkot developed such strictures, arguing that unaided human reason could not prove through a strict demonstration that any incorporeal being like an angel or God existed. The consequence for Holkot was that any reference to

such incorporeal beings found in the texts of ancient philosophers must have come down to them from their predecessors passing on a vestige of knowledge about God acquired ultimately from Adam and Eve. Holkot also contended that some pagans, who lacked the law of Moses, still received faith and grace from God outside the Mosaic Law because they did their best to live according to the principles of natural law. Holkot's sanguine view of pagan philosophers like Hermes Trismegistus and Aristotle rested not on their ability to use natural reason to discern theological truths, but on his confidence that God had accorded a measure of revelation to more than those who had the texts of scripture.

3.2 What reason can do

If basic theological premises require revelation for human beings to know them, then the arena of human reason in theology is restricted to reasoning about what is revealed. Some of the tenets of Christian doctrine, like the doctrines of the Trinity, Incarnation and Eucharist, offer particular challenges to logic. There was a general belief among medieval scholastics that Aristotelian logic exemplified natural reason at its best and was universally applicable to all domains because its rules held through formal relation to the principle of non-contradiction. If key Christian doctrines were not amenable to Aristotelian logical principles, however, it would seem to imply that God is not subject to the principle of non-contradiction and that Aristotelian logic is not universal. Holkot took up these issues in his discussion of the doctrine of the Trinity.

Difficulty arises in the doctrine of the Trinity over doctrinally true premises that seem to give rise to doctrinally false conclusions:

> The divine Essence is the Father,
>
> The divine Essence is the Son,
>
> Therefore, the Father is the Son.

Prior to Holkot, a variety of distinctions had been proposed to modify the identity relation of the copula in such premises and to block the conclusion. But Holkot objected that the divine Essence was in no way "really," "modally," "formally," "rationally," "convertibly," nor in any other way distinguished from the divine Persons or the divine relations of paternity, filiation and spiration. This put him back face to face with the dilemma.

Holkot responded in a passage for which he is perhaps best known, that there must be two systems of logic, a logic appropriate to the natural order, exemplified in Aristotle's works, and a logic appropriate to the supernatural order, a logic of faith, whose rules are supplementary to those of Aristotle. He concluded that Aristotelian logic did not hold universally, but only for the natural order unless additions were made to take into account theological cases. This did not mean that he abandoned the principle of non-contradiction in matters of faith. Rather the nature of the divine being meant that syllogisms involving Trinitarian terms functioned like expository syllogisms about particulars when unquantified universal

terms are substituted for particular ones:

> Human being is running,
>
> Human being is bald.
>
> Therefore, bald human being is running.

The conclusion is invalid because the subject term in each premise might stand for different people, like Plato and Socrates.

Holkot argued that since Aristotle could not have known about God as three Persons and one divine Essence, he could not have foreseen the need to adjust his logic for such cases, but with some supplementary rules taken from religious authority, like: "every absolute is predicated in the singular and not in the plural about the three persons," and "unity holds its consequent where the opposition of relation does not stand in the way" (*Sent.* I, q. 5, f. f2ra), Holkot believed the Trinitarian cases could be covered. The logic of faith does not have a large number of additional principles, and it, like Aristotelian logic, is rational because it is subject to the principle of non-contradiction.

Holcot's view of the relation between faith and reason was very much in the tradition of Anselm, of faith seeking understanding. His adherence to the principle of non-contradiction was uncompromising: "no intellect can assent to the opposite of the first principle or believe that contradictories are true at the same time" (*Quod.* I, q. 2, in *Exploring*, 38, ll. 165-166). Faith required that reason believe that all of the truths of the faith are compatible, even when at times they could not be demonstrated or shown to be so.

4. Necessity and Contingency

4.1 Historical context

The Condemnations of 1277 and John Duns Scotus impelled the view that the world could be other than it is. The idea that God's omnipotent power provides him with an infinity of choices out of which he chooses to create only one set of possibilities became a governing idea among subsequent English schoolmen. Scotus also argued forcefully for the idea that each moment was open to contingent possibility, such that for any time t, the events at t were possible not to be the events at t. Contingency, traditionally assigned to the future, in Scotus' view superceded or governed even the hypothetical necessity of the present. Ockham retreated from Scotus' view, reassigning contingency to future events and reasserting the full force of hypothetical necessity for events in the present. However, working out the implications for philosophy and theology of a contingent world order was the central intellectual challenge for Holkot's generation.

4.2 God's absolute and ordained power

Divine omnipotence involves the absolute power to enact anything that does not involve a contradiction. But among the multitude of possibilities open to divine enactment, God chooses or ordains a subset of compatible possibilities that constitute the world and its history as we know it. The relationship between God's absolute power and the ordained system in place at any given time provided a fault line for exploring questions of necessity and contingency. Thirteenth century theologians formulated the relationship as one between what God has done and what he could have done otherwise, safely relegating contingency to a now foreclosed past. Canon lawyers, however, appropriated the distinction to describe the powers of the pope to set aside "ordained" or enacted Church law through the "plenitude" or "absolute" power of his office. Because papal power transcended enacted law, and popes (and monarchs) who enacted laws were in some sense not subject to those laws, they could provide for exceptions or change enacted laws without contradiction. Such application of the distinction between absolute and ordained power raised the possibility that God might intervene in the ordained system through his absolute power. Beginning with Scotus, the formulation of the canonists began to enter into discussions of God's exercise of absolute power. The appropriation of the legal tradition did not lead to the conclusion (at least for Scotus, Ockham and Holkot) that God uses his absolute power to act inordinately in the ordained system, but rather it enables God (as it did in the change from the Old to the New Law) to set aside one ordained system and replace it with another. Several different and incompatible systems of divine legislation have operated at different times during human history. God's absolute capacity to transcend any given ordained system and replace it with another has made such a switch possible without involving God in a contradiction of his nature. Holkot also invoked this dialectical relationship between God's absolute and ordained power to explain how God provides for dispensations from his laws in particular cases. God never acts inordinately, but the system of divine ordinations is complex and involves multiple incompatible subsets capable of being in place at any given time.

Holkot analyzed God's power in terms of sets of compatible propositions.

> If all the propositions that can exist, were to exist, God cannot do what would entail contradictory propositions being true at the same time, and He can do all those things that, having posed them perfectly instantiated in being, entail no contradictory propositions being true at the same time. (*Sent*. II, q. 2, art. 6, f. i4va)

He then argued that talk of God's absolute and ordained power was not about a two-fold power, but two ways of modifying the proposition: "God can produce A." The proposition "God can produce A from his ordained power," means that it is possible for God to produce A, and A will be compatible with his existing statutes. The proposition "God can produce A from his absolute power," means that it is possible for God to produce A (because A in itself entails no contradictory propositions being simultaneously true), and A is not compatible with his existing statutes. God has only one power, which is God himself, and which human beings can understand in two different ways: ordinately and absolutely. (The stricture on propositional existence results from his view, which he shared with Ockham and a number of his contemporaries, that only propositional tokens counted as real propositions capable of producing a logical contradiction.)

The principle of non-contradiction served as the ultimate safeguard of rationality and certainty in Holkot's system. The role of the principle was particularly important because Holkot, more than perhaps any other late medieval theologian, underscored God's freedom to set aside ordained laws without incurring any fault or obstacle.

God can be obliged to no law but that without its observance he can be morally good, because otherwise the divine goodness would depend on creatures, and God would be less good than he is if he were to destroy every creature; and similarly God would begin to be better than he was before the observance of the law. Whence, just as a prince who is above the law can perform some act without sin or evil, which those existing under the law in no way can do without sin, so God in not fulfilling what he promised acts without the evil of falsity or perjury, which someone existing under the law could in no way do. (*Quodl*. III, q. 8, in *Seeing the Future*, 103, ll. 537-546)

Divine promises, revelations, and enactments were all in Holkot's view ungrounded in divine goodness in the sense that God was not under obligation because of his goodness to fulfill them or keep them in being. The contingency of the ordained system was a fact of the human condition. So what reassurance could human beings have that keeping faith with God's precepts would result in their salvation? What would happen if God were to set aside the current law and enact some incompatible alternative, as it would clearly seem to be in God's power to do? If God did not inform people about such a change, then invincible ignorance would protect them from being held accountable for not following the new laws. Holkot did not believe that God could ask people to obey laws of which they were ignorant because that would require them to do what is impossible and contradictory. And if God did inform people of the new laws, then these laws would supercede the incompatible old set, and the faithful could obey God without being held to contradictory commands.

5. Divine Command Ethics

5.1 Covenantal Theology

In a system of divine command ethics, human beings are obliged to do what God asks them to do because God commands it, not because there is some underlying system of absolute goodness that ethical precepts should ideally mirror. William Ockham had subscribed to such a view. He had argued that no contradiction would arise if God were to command that the Ten Commandments, the precepts fundamental to both the Old and New Laws, were no longer in effect and that from then on people would be obliged to obey their opposites. Most of Ockham's sympathizers backed away from the idea that God could command people to hate him, on the grounds that that command, at least, would be contradictory. But Holkot followed Ockham in subscribing to the ultimate contingency of the decalogue.

With no act having intrinsic worth, the meritoriousness of human behavior was grounded in a covenant between God and the human faithful. Within the terms of the New Law, God would not deny salvation to all those who did their best to obey his commands and adhere to the Articles of the Faith. The causal

effect of meritorious acts in effecting salvation was a secondary form of causality, functioning like money, as an agreed upon medium of exchange in the economy of salvation. Because God's goodness was not a guarantee of covenant, however, Holkot stressed that human adherence to the terms of the covenant constituted an act of faith that God would indeed uphold his promises, even knowing that nothing compels God to do so.

5.2 The significance of intention

Where the fact of command matters more than the substance of what is commanded, human intention to obey has greater significance than the substantive enactments of obedience. Holkot perceived the connection between divine command and the human intention to obey as at the heart of the relationship between human beings and God. For instance, Holkot posed the case of a simple old woman, who in good faith comes to church to hear a new church doctrine from her bishop. If the bishop gets the doctrine backwards, explaining to his congregation that they should believe just the opposite of what the new article of belief contains, is the elderly laywoman required to accept the words of her bishop as true? One of Holkot's fellow scholars had argued that she would only be in this position if she were being punished for sin, but Holkot responded that it was not the substance of her belief that mattered, but her intention to do what was right and to obey God. Her intention to do her best to conform her will to God would be sufficient under the covenant to ensure her salvation if she were to persevere in that intention. God would not deny her salvation because those on whom she necessarily depended for knowledge about God's will were misinformed or confused.

Debates over the place of deception in terms of both the absolute and ordained systems of possibility involved Holkot and a number of his immediate contemporaries. If the world is a contingent place that can be other than it is, then do God's revelations constrain the scope of his possible future actions? If not, can what God says be deceptive or false? Discussion took up scriptural instances in which God seemed to deceive. Holkot, against a number of his contemporaries, argued that God can deceive human beings even in the ordained system, has deceived them as shown in scripture, and has deceived them for no redeeming good apparent to human beings. If God's words to human beings might be deceptive, such that it is not just the bishop who may impart false information, but even God, then the human intention to believe God's words as true and to obey them takes on even more importance. Holkot did not believe that God was playing the role of Descartes' deceiving demon, but Holkot also did not know how to rule out the possibility that he might be deceived about any given thing he believed. The important thing was that even if he were deceived, God had promised that his intention to believe what was revealed and to do what he understood God wanted him to do provided security under the covenant. Faith in the covenant was the source of certainty, not rational demonstration.

The place of intentionality in Holkot's theology and his generous view of divine graciousness provide the context for his use of a version of what has come to be called "Pascal's wager." Holkot passed on a story about a learned heretic who was converted to a belief in immortality by a challenge from a Dominican lay brother: if you believe in immortality and it is true, you will have gained a great deal, and if you believe in immortality and it is not true, you will lose nothing. Forming an intention to believe could

constitute doing his best on the part of the heretic, and God would reward such an intention with the grace necessary for conversion to the belief.

6. Divine Foreknowledge

Discussions about the contingency of the created order and the various ways necessity might impinge on that contingency tended to focus on the challenge God's foreknowledge of future events posed to the contingency of events.

In his commentary on Peter Lombard's *Sentences*, Holkot put forward an elaborate argument:

> If *a* is a sin that Socrates will freely commit tomorrow.
>
> Then it is argued: God knows that *a* will be, therefore from eternity He knew that *a* will be or he began to know that *a* will be.
>
> It cannot be said that He began to know that *a* will be, because then He could know or foreknow something anew and as a result of time. . . .
>
> If He knew *a* from eternity, I pose that "*a* will be" was written on a wall yesterday. Therefore, the proposition "that written on the wall was true" is true, and . . . consequently necessary because it is a true proposition about the past. Therefore, it is necessary that it be the case as the proposition denotes, i. e., it is necessary that Socrates sin. (*Sent*. II, q. 2, in *Seeing the Future*, 126, ll. 307-317.)

Holkot contended that the common response of his era to such an argument, was to pose the possibility of a counterfactual past: to say that the proposition "*a* will be" is true, yet contingently true, and therefore, although it is true, it can never have been true. Holkot argued, the possibility of a counterfactual past differentiated propositions about the future on contingent matters and their equivalents--whether set in the past or present--from propositions about the past and present that are not about such contingent matters. The propositions "*a* was known by God," and "*a* is known by God," although set in the past and present, are true and yet can never have been true, just like other propositions about the future, because they are about *a*, and *a*, as a future contingent, may still not happen. Holkot's response is recognizable as a version of what in modern discussions is called the Ockhamist solution (although the argument traces back at least to Bonaventure).

6.1 The "obligational" model

What Holkot added to the discussion was an elaborate analysis of such puzzles using the rules and structure of obligational debates to explore counterfactual possibility. Debates *de obligatione* were a commonplace in the medieval university curriculum and involved one person, the "opponent" posing a

proposition to another, the "respondent," that, if accepted, would form the basis for a continuing exchange. The posed proposition was usually a counterfactual or a proposition whose truth status was uncertain. The opponent then proposed further propositions to the respondent, each of which might follow from, contradict or be irrelevant to the first. The respondent was to take the first proposition as true for the time of the debate (understood in Holkot's version to take place in a single hypothetical instant of time), and to respond with agreement or rejection depending on whether the succeeding propositions followed from what had been agreed on before or contradicted the preceding concessions. If a proposed proposition was unconnected with any of the preceding propositions, the respondent would respond with agreement, rejection or doubt depending on what he understood the actual state of affairs in the world to be. The forms and rules of obligational debate suggested a rigorous format for exploring the contingent possibilities, which Holkot adopted.

A simple form of the puzzle might proceed as follows:

> Opponent: Let it be the case that God knows *a* will be, where *a* is a future contingent.
>
> Respondent: I accept.
>
> Opponent: Everything that is possible to be is also possible not to be (by the definition of contingency).
>
> Respondent: I accept.
>
> Opponent: As a future contingent, *a* is possible to be and possible not to be.
>
> Respondent: I accept.
>
> Opponent (from the Aristotelian rule that the impossible does not follow from the possible): Let it be the case that *a* will not be.
>
> Respondent: I accept.
>
> Opponent: Then God is deceived.

In resolving such puzzles, Holkot invoked a series of rules, one of which has significance for his moral philosophy, as well. Holkot argued that when the opponent proposed the initial proposition, he was also implicitly posing the rejection of its contradictory. The Aristotelian rule that the impossible does not follow from the possible, seems to allow the contradictory of the initial proposition to enter the debate. But Holkot argued that such a move in effect amounted to starting the debate all over again with a new starting point, a proposition contradictory to the first. The respondent would now be obliged, if he continued with the debate, to answer in accordance with the new contradictory proposition, and would refuse to concede that "God is deceived."

Holkot viewed the human relationship to divine revelation as equivalent to engaging in an obligational debate. The faithful obligated themselves to accept divine revelations as true for the time of this life (even though as contingents it was possible that they might not be true), and if God commanded them to act in a way contrary to previous commands, the new commandment would supercede the old, just if a new obligational debate had begun. Those who accepted the obligation to obey, would also be obligated to live in a way that was consistent with the obligations incurred, even if God did not reveal the details. Human reason was required to discern how to act in uncertain cases.

6.2 The modal ground of experience

In dealing with the problem of God's knowledge of future contingents, Ockham had proposed thinking about time as the modal feature of language. Propositions in the past tense are necessary *per accidens*: they refer to events that could have been otherwise before they happened, but that now could not have been other than they were because of the necessity of the past. Propositions in the present tense are hypothetically necessary: they refer to events that could be otherwise, but given that they are what they are, if they are, cannot not be what they are. Propositions in the future tense are contingent: they refer to events that are possible to be and also possible not to be. Ockham argued that God's knowledge of events tracked this modal arrow just as human knowledge of events does, reintroducing an arrow of "time" for God as well as human beings.

In the ensuing years, Ockham's modal view of "time" was joined to a way of speaking about truth traceable to Richard of Campsall, an Oxford master of arts and theology teaching in the years just before Ockham. Holkot exemplifies this way of thinking.

In *De Interpretatione*, chapter 9, Aristotle had bequeathed a difficult problem to the medieval debate about divine foreknowledge. His contention that in order to avoid attaching necessity to all events, propositions about future events were not yet true or false seemed to deny to God the possibility of knowing the future or to rule out the contingency of events. Boethius had provided a response that held until the fourteenth century, but after Scotus subjected his response to a severe critique, new discussion of the Aristotelian three-valued logic appeared. Campsall distinguished between propositions about the past and present that were "determinately true or false" and propositions about the future that were "indeterminately true or false." Holkot adopted this way of modally dividing up determinations of truth and falsity:

> . . . future contingents are said to be propositions about the future of which there is no determinate truth or falsity, because although they are true or false, yet those which are true can never have been true and those which are false can never have been false. (*Quod.* III, q. 1, in *Seeing the Future*, 63, ll. 93-96.)

By the time of Holcot, the analysis of future contingency in terms of a possible counterfactual past, and the identification of such an analysis with a multi-valued logic, had attained the status of an identifiable

tradition. Ockham had not adopted the terminology of "indeterminately true or false" and "contingently true or false" to speak of the truth status of future contingent propositions. He had insisted on a two-valued system in which all propositions are determinately true or false. But Holkot departed from him in this. Holkot's position reflects a view of modality as primary. Necessity and contingency are fundamental, and judgments of truth mean something different in each modal context, rather than truth being primary, and necessity and contingency providing a different valence to otherwise true propositions. The efforts to grapple with the implications of contingency had come a long way.

Epistemological Problems of Perception

The historically most central epistemological issue concerning perception, to which this article will be almost entirely devoted, is whether and how beliefs about physical objects and about the physical world generally can be justified or warranted on the basis of sensory or perceptual experience -- where it is *internalist* justification, roughly having a *reason* to think that the belief in question is true, that is mainly in question (see the entry justification, epistemic: internalist vs. externalist conceptions of). This issue, commonly referred to as "the problem of the external world," divides into two closely related sub-issues, which correspond to the first two main sections below. The first of these issues has to do with the nature of sensory experience and its relation to the physical world; it is typically (though as we shall see not altogether perspicuously) formulated as the question of what are the *immediate* objects of awareness in sensory experience or, in a variant but essentially equivalent terminology, of what is *given* in such experience. Perhaps the most historically standard, though not currently the most popular answer to this question has been that it is *sense-data* (private, non-physical entities actually having the experienced sensory qualities) that are the immediate objects of awareness or that are given. The second issue has to do with the way in which beliefs about the physical world are justified on the basis of such sensory experience. If it is concluded that physical objects are not themselves given, the two main answers to this question are *representationalism* (the view that the immediate objects of experience represent or depict physical objects in a way that allows one to infer justifiably from such experience to the existence of the corresponding "external" objects) and *phenomenalism* (the view that physical objects are reducible to or definable in terms of the occurrence and obtainability of such experience). A third alternative view that has received attention in recent discussion is *direct realism*: the view that physical objects are after all directly or immediately perceived in a way that allegedly avoids the need for any sort of justificatory inference from sensory experience to physical reality. In addition to these views concerning the internalist justification of beliefs about physical objects, there are also externalist accounts of how such beliefs are justified; these will be briefly considered at the end of the article.

---

1. The Nature of Sensory Experience

What is it that we are *immediately* or *directly* aware of in sensory or perceptual experience? Is it public physical objects, private sensory entities of some sort, or perhaps some still further sort of entity (or state)?

1.1 The idea of immediacy or givenness

Before considering answers to this question, it is important to become clearer about the meaning of the question itself. What is it for something to be an object of *immediate* (or *direct*) awareness or to be given? (For brevity I will mostly employ the latter term.)[1] Historically, most of those (beginning with Descartes and Locke) who have attempted to answer this question have concluded that it is something other than a physical object that is given, but the reason for this conclusion cannot be understood without becoming clearer about the idea of immediacy or givenness itself.

There are two more or less standard criteria of givenness that have at various times been offered, either jointly or separately, but these unfortunately do not seem to work very well. The first of these appeals to the idea of *inference*: something is immediately experienced or is given if the cognitive consciousness of it is not arrived at via any sort of inferential process. The obvious problem with this is that it makes it hard to make sense of the historically common view that physical objects are not given, since the sensory awareness of physical objects in the most normal sorts of cases does not *seem* on the surface to be a product of inference. Certainly the person who has such an awareness is not normally conscious of having made an inference; and to insist, as is sometimes done, that there must have been an "unconscious inference" of some sort could only be justifiable if some other criterion of givenness is being at least tacitly invoked. It is somewhat more plausible to hold that beliefs about physical objects, even if not arrived at via inference, must still be inferentially *justified*, but neither the rationale for such a claim nor its relation to the idea of givenness or immediacy is clear at this point.

The second of the standard criteria appeals to the idea of *certainty*: something is immediately experienced or given if the awareness of it is certain, incapable of being mistaken. But while it is plausible enough that all perceptual awareness of physical objects is at least in principle subject to error,

it is less clear that there is *anything* generally present in sensory or perceptual experience about which error is impossible; beliefs about any aspect of experience, involving as they do the need for conceptual classification, are always capable in principle of being mistaken. Nor, for that matter, is it clear why if some sort of item did have this status, this would show that the awareness of it is more fundamental in the way that the idea of immediacy or givenness seems to suggest, and in particular why beliefs about physical objects must be somehow based on the awareness of this other sort of item.

On the basis of difficulties like these, it has sometimes been concluded that the idea of immediacy or givenness is hopelessly obscure, with the implication being that there is no reason why the perceptual awareness of physical objects should not be itself regarded as epistemically fundamental, not needing to be justified by appeal to a more basic awareness of sense-data or of anything else. This is at least part of the motivation for direct realist views (see below).

But such a conclusion (as is suggested in part by the difficulties that arise in making clear sense of direct realism) seems too hasty. My suggestion instead would be that the underlying conception of immediacy or givenness, of which the foregoing criteria are best regarded as merely symptoms, is that for something to be given is simply for it to be an aspect or feature of the content of conscious experience itself (as distinct from the intentional objects that such conscious content may in part be about). On this conception, much more is given than sensory content narrowly construed: conscious feelings, the conscious aspects of emotions, and most importantly the conscious contents of thoughts or beliefs. But it also seems clear that there is a narrowly sensory component, consisting of or involving colors, shapes, sounds, tactile qualities of various sorts, etc. And although more detailed arguments will be considered shortly, it also seems more or less undeniable that physical objects, at least as commonsensically construed, are not themselves literally part of that conscious content, even though they are depicted or represented by various aspects of it.

1.2 The Sense-Datum Theory

As already remarked, the most widely held view historically concerning the strictly sensory aspect of immediate or given experience is that what is given in such experience is, not public physical objects, but rather *sense-data* (or sometimes *sensa*): private, non-physical entities that actually possess the various sensory qualities that a person experiences. (For a variant usage of this term, see Moore [1953], who there uses the term "sense-datum" to stand for *whatever* it is that is immediately experienced or given, possibly even a public physical object, and then argues somewhat tentatively that the entities that actually have this status are sense-data in the more usual sense, rather than physical objects.)

Two main arguments have been offered for this view.

The Argument from Illusion

(Or, perhaps better, the argument from illusion/perceptual relativity/hallucination.) This very widely advocated argument (first offered explicitly in Berkeley [1713]) appeals to the immense variety of cases

in which: (i) what is immediately perceived or given has different qualities from different perspectives or under different perceptual conditions, even though the relevant physical object does not change (perceptual relativity); or (ii) in which qualities are immediately experienced that the relevant object clearly does not possess (illusion); or (iii) in which qualities are experienced in a situation in which there is no physical object of the relevant sort present at all (hallucination). Some fairly standard examples: viewing a circular coin from different angles, resulting (allegedly) in the experience of a variety of elliptical shapes; viewing a white or colored object under different kinds of lighting; feeling the temperature of a luke-warm bucket of water with a hand that has previously become inured to water of substantially higher or lower temperatures; viewing a straight stick that is immersed in water and so looks bent; hallucinating a non-existent object such as pink rat or a dagger.

The basic claim is that in cases of illusion or hallucination, the object that is immediately experienced or given has qualities that no public physical object in that situation has and so must be distinct from any such object. And in cases of perceptual relativity, since objects with different qualities are experienced from each of the different perspectives or under each of the relevant conditions, at most one of these various immediately experienced or given objects could be the physical object itself; it is then further argued that since there is no apparent experiential basis for regarding one out of any such set of related perceptual experiences as the one in which the relevant physical object is immediately experienced, the most reasonable conclusion is that the immediately experienced or given object is always distinct from the physical object (or, significantly more weakly, that there is no way to identify which, if any, of the immediately experienced objects is the physical object itself, so that the evidential force of the experience is in this respect the same in all cases, and it is epistemologically as though physical objects were never given, whether or not that is in fact the case).

The cogency of this argument has been challenged in a number of different ways, of which the most important are the following. First, it has been questioned whether there is any reason to suppose that in cases of these kinds there must be some *object* present that actually has the experienced qualities, which would then seemingly have to be something like a sense-datum. Why couldn't it be the case that the perceiver is simply in a state of seeming to experience such an object without any object actually being present? (See the discussion below of the adverbial theory.) Second, it has been argued that in cases of illusion and perceptual relativity at least, there is an object present, namely the relevant physical object, which is simply misperceived, for the most part in readily explainable ways. Why, it is asked, is there any need to suppose that an additional object is also involved? Third, the last part of the argument has been challenged, both (i) by questioning whether it is really true that there is no experiential difference between veridical and non-veridical perception; and (ii) by arguing that even if sense-data are experienced in non-veridical cases and if the difference between veridical and non-veridical cases is, after all, experientially indiscernible, there is still no reason to think that sense-data are the immediate objects of experience in veridical cases. Fourth, various puzzling questions have been raised about the nature of sense-data: Do they exist through time or are they momentary? Can they exist when not being perceived? Are they public or private? Can they be themselves misperceived? Do they exist in minds or are they extra-mental even if not physical? On the basis of the intractability of these questions, it has often been argued that the conclusion of the argument from illusion is clearly unacceptable or even ultimately unintelligible, even in the absence of a clear diagnosis of exactly where and how it goes

wrong.[2]

The Argument from the Scientific Account of Perception

A second argument for the conclusion that sense-data, rather than physical objects, are the direct or immediate objects of even veridical perceptual experience appeals to the causal account of the perceptual process offered by natural science. The main aspects of that account that are cited in this connection are: (i) the fact that the character of the resulting experience and of the physical object that it seems to present can be altered in major ways by changes in the conditions of perception or the condition of the relevant sense-organs and the resulting neurophysiological processes, with no change in the external physical object (if any) that initiates this process and that may seem to be depicted by the experience that results; (ii) the related fact that any process that terminates with the same sensory and neural results will yield the same perceptual experience, no matter what the physical object (if any) that initiated the process may have been like; and (iii) the fact that the causal process that intervenes between the external object and the perceptual experience takes at least a small amount of time, so that insofar as the character of the experience reflects the features of that object, they reflect an earlier stage of that object rather than the one actually existing at that moment. (In extreme cases, as in astronomical observation, the external object may long ago have ceased to exist by the time it is perceived.) These facts are claimed to point inexorably to the conclusion that the direct or immediate object of such an experience, the object that is *given*, is an entity produced at the end of this causal process and is thus distinct from the physical object, if any, that initiates the process.

It is difficult to resist the conclusion that there is a fundamental distinction between the external object, if any, that initiates the perceptual process and the perceptual experience that eventually results, thus amounting to a fundamental *dualism* between perceptual experience and the external object and raising the issue of how the latter can be known on the basis of the former. What can and has been resisted, by the adverbial theory in particular, is the idea that this dualism is a dualism of *objects*, with perceptual experience being a more direct experience of objects of a diffeent sort, sense-data. (Though we will eventually see that the result of balking at this point may have less epistemological significance than it has usually be accorded.)

1.3 The Adverbial Theory

The sense-datum theory is often characterized as an *act-object* theory of the nature of immediate experience: it accounts for such experience by postulating both an *act* of awareness or apprehension and an *object* (the sense-datum) which that act apprehends or is aware of. The fundamental idea of the adverbial theory, in contrast, is that there is no need for such objects and the problems (such as whether they are physical or mental or somehow neither) that they bring with them. Instead, it is suggested, merely a mental act or mental state with its own intrinsic character is enough to account for the character of immediate experience.

According to the adverbial theory, what happens when, for example, I immediately experience a silver

elliptical shape (as when viewing a coin from an angle) is that I am in a certain specific state of sensing or sensory awareness or of *being appeared to*: I sense in a certain manner or am appeared to in a certain way, and it is that specific manner of sensing or way of being appeared to that accounts for the specific content of my immediate experience. This content can be verbally indicated by attaching an *adverbial* modifier to the verb that expresses the act of sensing (which is where the label for the view comes from). Thus in the example just mentioned, it might be said that I sense or am appeared to *silver-elliptical-ly* -- where this rather artificial term is supposed to express the idea that the qualitative content that is treated by the sense-datum theory as involving features or properties of an object should instead be thought of as somehow nothing more than the specific manner in which I sense or the specific way in which I am appeared to. Similarly, when I hallucinate a pink rat, I sense or am appeared to *a-pink-rat-ly* -- or, perhaps better, *a-pink-ratshape-ly*. And analogously for other examples of immediate experience.

The essential point here is that when I sense or am appeared to silver-elliptical-ly, there need be nothing more going on than that I am in a certain distinctive sort of experiential state. In particular, there need be no object or entity of any sort that is literally silver and elliptical -- not in the material world, not in my mind, and not even in the realm (if there is such a realm) of things that are neither physical nor mental.

1.4 Conclusion Concerning the Sense-Datum and Adverbial Theories

Each of these two views has fairly obvious virtues and equally obvious drawbacks. The sense-datum theory accounts more straightforwardly for the character of immediate experience. I experience a silver and elliptical shape because an object or entity that literally has that color and shape is directly before my mind. But both the nature of these entities and (as we will see further below) the way in which they are related to the mind are difficult to understand.

The adverbial theory, on the other hand, has the advantage of being metaphysically simpler and of avoiding difficult issues about the nature of sense-data.[3] The problem with it is that we seem to have no real understanding of the nature of the states in question or of how exactly they account for the character of immediate experience. It is easy, with a little practice, to construct the adverbial modifiers. But it is doubtful that anyone has a very clear idea of the meaning of such an adverb, of what exactly it says about the character of the state -- beyond saying merely and unhelpfully that it is such as to *somehow* account for the specific character of the experience.

Here I will limit myself to a brief consideration of one further, less obvious argument against the sense-datum theory and in favor of the adverbial theory, and to pointing out why the issue between these two views, though of great metaphysical significance, may not matter very much if at all for epistemological purposes. As we have so far characterized it, the sense-datum theory is incomplete in one fundamental way. In addition to arguing that sense-data exist, a sense-datum theorist needs some account of the relation between a person and a sense-datum when the former immediately experiences the latter. It does not seem acceptable to say that simply that the sense-datum is itself in the mind, a mental entity, since it has features which neither an immaterial mind nor the physical brain seem capable of possessing. The natural thing to say is that the sense-datum somehow influences the internal state of the person (that is, of

his or her mind) in a way that reflects the sense-datum's specific character. But the resulting state of mind would then be just the sort of state that the adverbial theory describes, one which is such that a person who is in it will thereby experience the properties in question. And there would then be no apparent reason why such a state could not be produced directly by whatever process is supposed to produce the sense-datum, with the latter thus becoming an unnecessary intermediary. Thus the sense-datum theorist must apparently say that the immediate experience of the sense-datum does not involve any distinct internal state of the person that reflects its character, but is instead an essentially and irreducibly *relational* state of affairs. The person simply experiences the sense-datum, but without there being any corresponding change in his or her internal states that would adequately reflect the character of the supposed sense-datum and so make its existence unnecessary in the way suggested. But does this really make good metaphysical sense, and, more importantly, would it allow the person to grasp or apprehend the nature of the sense-datum in a way that could be the basis for further justification and knowledge?

Both views thus have serious problems, though, in light of the last argument, I would assess the problems of the sense-datum theory as the more serious. Fortunately, however, as already suggested, it does not seem necessary for strictly *epistemological* purposes to decide between these two views. The reason is that while they give very different accounts of what is ultimately going on in a situation of immediate experience, they make no difference with respect to the experienced content of that experience. And it is on that experienced content, not on the further metaphysical explanation of it, that the justificatory power, if any, of such an experience depends.

2. The Justification of Beliefs about the Physical World

In considering this second issue, it will be useful to begin by assuming, subject to later reconsideration, that *either* the sense-datum theory or the adverbial theory is correct: that what we are *immediately* aware of in sensory experience is never an external material object, but is either a sense-datum or else the content of a state of sensing or being appeared to. It will be useful to have a brief label for this disjunctive position, and I will refer to it here as *perceptual subjectivism*.[4] In fact, I will usually, for the sake of simplicity, formulate the issues to be considered in terms of sense-data, leaving the adverbial variant to be supplied by the reader.[5]

Assuming perceptual subjectivism, there are two main non-skeptical alternatives regarding the justification of beliefs concerning material objects on the basis of immediate experience. The more obvious and historically prior view, at least approximated by Descartes and Locke, is *representationalism* or *representative realism*: the view that our subjective sensory experience (and the beliefs that we adopt on the basis of it) constitute a *representation* of the external material world, one that is caused by that world and that we are justified, on the basis of something like a causal or explanatory inference, in thinking to be at least approximately accurate. The second main view is that (i) we can have no knowledge (or perhaps even no intelligible conception) of a realm of external causes of our experience, but also (ii) that our beliefs about the material world can still be in general justified and true

because their content pertains only to the features and order of our subjective experience. This is the view that has come to be known as *phenomenalism*.[6] It will be convenient to begin with the latter of these two views, which was widely held for at least a good part of the 20th century.

2.1 Phenomenalism

As just briefly formulated, the phenomenalist view is that the content of propositions about material objects and the material world is *entirely* concerned with features and relations of the immediate objects of our perceptual experience, that is, the features and relations of our sense-data.[7] According to the phenomenalist, to believe that a physical or material object of a certain sort exists is just to believe that sense-data of various sorts have been experienced, are being experienced, will be experienced, and/or would be experienced under certain specifiable conditions. Thus, for example, to believe that there is a large brown table in a certain room is to believe, roughly, (i) that the sorts of sense-data that seem from a common-sense standpoint to reflect the presence of such a table either have been, are presently, or will in the future be experienced in the context of other sense-data, themselves experienced concurrently or immediately before or after, that reflect the location as the room in question; and in addition -- or instead, if the table has never in fact been perceived and never in fact will be perceived -- (ii) that such sense-data *would* be experienced *if* other sense-data that reflect the perceiver's going to that room were experienced.

In a fairly standard formula, to believe that such a material object exists is, according to the phenomenalist, to believe nothing more than that sense-data of the appropriate sort are actual (in the past, present, or future) and/or possible -- where to say that certain sense-data are *possible* is to say, not just that it is *logically* possible for them to be experienced (which would apparently always be so as long as the description of them is not contradictory), but that they would in fact be experienced under certain specified circumstances (themselves specified in sense-datum terms); thus it would be clearer to speak of actual and *obtainable* sense-data. John Stuart Mill put this point by saying that material objects are "permanent possibilities of sensation,"[8] that is, of sense-data -- where, of course, the possibilities in question are only *relatively* permanent, since objects can change or be destroyed.

The main argument for this commonsensically implausible view derives from Hume [1739-40]. One premise is the Humean idea that causal relations can be known only by experience, so that there is no way in which a causal relation between the immediate content of experience and something outside that immediate content could be known (and hence also no way to justifiably invoke such external causes as explanations of that experience). The other main premise is simply the common-sense conviction that skepticism is false, that we do *obviously* have justified beliefs and knowledge concerning ordinary objects like trees and rocks and buildings and about the material world in which they exist. And the argument is then just that the only way that such justified beliefs and knowledge are possible, given that no causal or explanatory inference from immediate experience to material objects that are genuinely external to that experience could ever be justified, is if the content of our beliefs about the material world does not really have to do with objects existing outside our immediate experience, but instead pertains just to that experience and the order that it manifests. Most phenomenalists will admit that this seems initially implausible, but will try to argue that this apparent implausibility is in some way an illusion, one

that can be explained away once the phenomenalist view and the considerations in favor of it have been fully understood.[9]

Objections to Phenomenalism

Many, many objections and problems that have been advanced in relation to phenomenalism. Here we will be content with a few of the most interesting ones:

Consider, first, what is perhaps the most obvious question about the phenomenalist view: *Why*, according to the phenomenalist, are the orderly sense-data in question obtainable or "permanently possible?" What is the *explanation* for the pattern of actual and obtainable sense experiences that constitutes the existence of a material object or of the material world as a whole, if this is not to be explained by appeal to genuinely external objects? The only possible phenomenalist response to this question is to say that the fact that sensory experience reflects this sort of order is simply the most fundamental fact about reality, not further explainable in terms of anything else. For *any* attempted further explanation, since it would obviously have to appeal to something outside of that experience, would be (for the reasons already discussed) unjustified and unknowable. (The phenomenalist will add that it is obvious anyway that not everything can be explained, since each explanation just introduces some further fact for which an explanation might be demanded.)

But it seems both quite implausible to suppose that something as large and complicated as the total order of our immediate experience has no explanation at all -- and also very obvious that common sense (at least if it accepted perceptual subjectivism) would regard claims about material objects as providing such an explanation, rather than as just a redescription of the experiential order itself (as the phenomenalist claims). Perhaps, for all we have seen so far, the phenomenalist is right that we cannot ever know that any such explanation is correct, but this, if so, is an argument for *skepticism* about the material world, not a justification for perversely reinterpreting the meaning or content of claims about material objects. (Here it is important to be clear that phenomenalism is *not* supposed to be a skeptical view, but rather an account of how beliefs about material objects are indeed justified and do constitute knowledge -- given the phenomenalist account of the content of such beliefs.)

A second problem (or rather a set of related problems) has to do with the specification of the conditions under which the various sense-data that (according to phenomenalism) are what a material-object proposition is about either are or would be experienced. It is clear that such conditions must be specified to have even a hope of capturing the content of at least most such propositions in sense-datum terms. To recur to our earlier example, to say merely that the sense-data that are characteristic of a brown table are actual or obtainable in some circumstances or other may perhaps capture the content of the claim that the world contains at least one brown table (though even that is very doubtful), but surely not of any more specific claim, such as the one about such a table being in a particular room. For that, conditions must be specified that say, as it were, that it is in relation to that particular room that the sense-data are or would be experienced. (But for the phenomenalist, the room does not of course exist as a mind-external place; talk of a room or of any physical location is to be understood merely as a way of indicating one aspect of

the order of immediate experience.)

What makes this problem extremely difficult is that for phenomenalism to be a viable position, the conditions under which sense-data are experienced or obtainable must themselves be specifiable in terms of *other sense-data*, not in terms of material objects and structures such as the library or room in question. For the essential claim of phenomenalism is that the content of propositions about material objects can be *entirely* specified in terms of sense-data. If in specifying the conditions under which the actual and obtainable sense-data relevant to one material-object proposition would occur, it were necessary to make essential reference to other material objects, then the account of the content of the first proposition would not yet be completely in sense-datum terms. And if in specifying the conditions relevant to claims about those other material objects, still other material objects would have to be mentioned, and so on, then the phenomenalist account would never be complete. If the content of propositions about material objects cannot be given *entirely* in terms of sense-data, if that content involves essential and ineliminable reference to further such objects, then phenomenalism fails.

How then can the idea that sense-data are or would be observed in a certain location be adequately captured in purely sense-datum terms? The natural response, which was in effect invoked when the example was originally discussed, is to appeal to the idea of a *sensory route*: a series of juxtaposed and often overlapping sense-data that would be experienced in what we think of intuitively as moving to or approaching the location in question. But there are at least two serious problems about this answer, however. One is that there are normally *many* different sensory routes to a given location, depending on where one starts; and if the starting location is itself determined by a previous sensory route, then a regress threatens, in which the sensory conditions must go further and further back in time without ever reaching a place from which they can unproblematically begin. A second problem is that it seems clear that we can often understand the claim that a certain material object or set of objects exists at a certain physical location without having any clear idea of the relevant sensory route: for example, I understand the claim that there are penguins at the South Pole, but have no idea of the sensory route that I would have to follow to guarantee that I have reached the South Pole. (Note that it is a *guarantee* that is required, for otherwise the content of the claim in question as not been fully captured.)[10]

A related, but still much more difficult problem of what the phenomenalist can say about the content of propositions about material objects and events in the past, perhaps the very distant past. Under what sensory conditions would sense-data of a tree have to have been obtainable to make it true that there was a pine tree in the place now occupied by my house in 1000 B.C.? It is thus very doubtful that the sort of specification of conditions that the phenomenalist needs is possible in general.

A generalization of this objection is offered by Roderick Chisholm.[11] Chisholm argues that there is in fact *no* conditional proposition in sense-datum terms, however long and complicated the set of conditions in the "if" part, that is *ever* even part of the content of a material-object proposition. This is shown, he claims, by the fact that for any such sense-datum proposition, it is *always* possible to describe conditions of observation (including conditions having to do with the state of the observer) under which the sense-datum proposition would be false, but the material-object proposition might still be true. The idea here is

to describe various sorts of abnormalities pertaining to the conditions or the observer: for example, having followed the sensory route to the room in the library, I am suddenly struck blind or knocked unconscious or injected with a mind-altering drug at just the instant before I would experience the distinctive table sense-data, which thus are not experienced (or the lighting is so altered as to make it impossible to see the table or to make it look very different in color; or the table is dropped through a trap door in the floor, to be restored only after I leave; etc.). Chisholm's suggestion is that the only way to guarantee that the sense-data that are experienced reflect the object that is actually there is to specify the conditions in *material* terms. But in that case, for the reason already discussed, the phenomenalist project cannot succeed.

A third, somewhat related, but deeper problem[12] arises by reflecting that it is apparently a condition for the success of phenomenalism that the realm of sense-data have an intrinsic order of its own, one that can be recognized and described solely in terms of the sense-data themselves. For how could we (without invoking independent material objects) have any justification for thinking that further sense-data will, under various conditions, occur, except by finding regularities in those we actually experience and reasoning inductively? But does such an intrinsic order of sense-data really exist? It is obvious that our sense-data are not merely chaotic, but far less obvious that they have an order that can be captured without making reference to material objects. And this is not something that the phenomenalist can just assume, for it is utterly essential to his whole position.

A fourth and final objection to phenomenalism, one that is much simpler and more straightforward, concerns what the phenomenalist must apparently say about the knowledge of the mental states of people other than myself (or other than whoever is thinking about the issue). The whole thrust of the phenomenalist position, as we have seen, is that *any* inference beyond immediate experience is impossible, that claims that might seem to be about things outside of experience must, if they are to be justified and knowable, be understood as pertaining only to features and orderly patterns of that experience. But the mental states of *other* people, their experiences and feelings and conscious thoughts, are surely outside of *my* immediate experience. Indeed, to reach justified conclusions about what people distinct from me are genuinely thinking and experiencing apparently requires *two* inferences: first, an inference from my immediate experience of sense-data pertaining to their physical bodies to conclusions about those bodies; and then, second, an inference from the facts about those bodies thus arrived at to further conclusions about the minds and mental states of the people in question. *Both* of these inferences depend on causal relations that are, according to the phenomenalist, unknowable, because we cannot experience both sides, or in the second case even one side, of the relation; and thus neither inference, construed in that way, is justified according to the basic phenomenalist outlook.

What phenomenalism must apparently say here, in order to be consistent, is: (i) that the content of propositions about the conditions and behavior of other people's bodies, like that of all other material object propositions, pertains only to facts about *my* immediate experience; and (ii) that the content of further claims about the mental states associated with those bodies is only a further, more complicated and less direct description of, once again, *my* experience. Though the phenomenalist would perhaps resist putting it this way, the upshot is that *my* mind and mental states, including my immediate experience, is the only mind and the only collection of mental states that genuinely exist, with claims that are

apparently about other minds amounting only to further descriptions of this one mind and its experiences. This is the view known as *solipsism*. It seems clearly to be an absurd consequence, thus yielding a really decisive objection, if one were still needed, to phenomenalism.

2.2 Representationalism

If phenomenalism is indeed untenable, and assuming that we continue to accept perceptual subjectivism, then the only non-skeptical alternative apparently left is *representationalism*: the view, restating it a bit, that our immediately experienced sense-data, together with the further beliefs that we arrive at on the basis of them, constitute a *representation* or depiction of an independent realm of material objects -- one that we are in general, according to the representationalist, justified in believing to be true.

Defenses of representationalism have taken a variety of forms, but I will assume here that the best general sort of defense for such a view is one along the lines suggested, albeit not very explicitly, in Locke (and indeed also, though even less explicitly, in Descartes). The central idea is, first, that (contrary to the claim of the phenomenalist) some *explanation* is needed for the complicated and intricate order that we find in our (involuntarily experienced) sense-data (or adverbial contents); and, second, that the *best* explanation, that is, the one most likely to be correct, is that those experiences are caused by and, with certain qualifications, systematically reflect the character of a world of genuinely independent material objects, which we accordingly have good reasons for believing to exist.

It is this appeal to what has come to be referred to as "inference to the best explanation" that allegedly provides an answer to the Humean argument, by allowing the supposed causal and explanatory relation between material objects and sensory experience to be known or justifiably believed in despite the fact that it cannot itself be immediately experienced. A consideration of the merits of this general idea of explanatory or abductive inference is beyond the scope of the present article [see abduction]. Here we will be concerned solely with whether and to what extent representationalism can be defended, given the fairly widely accepted assumption that such reasoning is in general cogent.

The Representationalist Explanation of Experience

Before considering whether the representationalist explanation of sensory experience is really the *best* one, we need to consider in more detail what the rationale for that explanation might be.

The place to start is to ask what it is about the character of our immediate sensory experience that points to or perhaps even seems to demand such an explanation. In perhaps the earliest very explicit discussion of this issue, Locke[13] points to two features of our experience in this connection: (i) its involuntary character, i.e., the fact that it simply occurs without any choice or control on the part of the person having the experience; (ii) the systematic order or coherence of that experience. But while these features may indeed demand *some* sort of explanation, they do not, at least when described at that level of abstraction, point at all clearly at the specific one that the representationalist favors. Why shouldn't these features of experience be explained in some quite different way, such as the one proposed by Berkeley (and

considered by Descartes): by appeal to a deity or similar being who causes the experience in us?[14] If anything about experience does points to Locke's explanation rather than Berkeley's, it will have to be something more specific than the features mentioned by Locke.

My tentative suggestion is that there are at least two aspects of the order of experience that suggest and might indeed seem to demand the representationalist's explanation in terms of external material objects. The first is the presence in immediate experience of repeatable sequences of experienced qualities that overlap and often shade gradually into one another. Here I have in mind something like the "sensory routes" that were, as discussed earlier, invoked by the phenomenalist. While these "sensory routes" cannot ultimately do the job that the phenomenalist needs them to do, for the reasons given there, they are nonetheless very real and pervasive. Think of the ways in which such "sensory routes" can be experienced in opposite orders (imagine here what common sense would regard as walking from one place to another and then returning to the first place by the same route -- perhaps even walking backwards, so as to make the two sequences as similar as possible). Think of the ways in which such "sensory routes" intersect with each other, thus, for example, allowing one to get from one end to the other without going through the "route" itself, thereby delineating a sensory loop. Think of the resulting structure of a whole set of overlapping and intersecting "sensory routes."[15]

The idea is then that at least the most obvious and natural explanation of these features of our experience is that we are located in a 3-dimensional spatial realm of objects through which we move and of which we can perceive at any given moment only the limited portion that is close enough to be accessible to our various senses (what this requires differs from sense to sense). Our experience reflects both the qualities of these objects and the different perspectives from which they are perceived as we gradually approach them from different directions, at different speeds, under different conditions of perception, etc. It is thus the relatively permanent structure of this spatial array of objects that is reflected in the much more temporary and variable, but broadly repeatable features of our immediate experience.

The second, and even more important aspect of immediate experience that points to the representationalist explanation is the fact, already noticed in our discussion of phenomenalism, that the order just indicated, though undeniably impressive, is in fact *incomplete* or *fragmentary* in a number of related ways. The easiest way to indicate these is by reference to the sorts of situations that, from a common-sense standpoint, produce and explain them (though the representationalist cannot, of course, assume at this stage, without begging the question, that these situations are what is actually occurring). Imagine then traversing a "sensory route" of the sort just indicated, but doing so: (i) with one's eyes closed (or one's ears plugged, etc.) during some of the time required, or perhaps while asleep during part of the time (traveling in a car or train); or (ii) while the conditions of perception, including those pertaining to the functioning of your sense-organs and to your mental "processing", are changing or being varied (involving such things as changing lighting, including complete darkness; jaundice and similar diseases that affect perception; objects and conditions that temporarily block or interfere with perception; even something as simple as turning one's head in a different direction, blinking, or wiping one's eyes). Reflection on cases like these show that the sensory sequences that define the various "sensory routes" are in fact substantially less regular and dependable than they might at first seem.

Thus the representationalist can in effect argue that the realm of immediate sensory experience, of sense-data (or adverbial contents), is both *too* orderly not to demand an explanation and *not orderly enough* for that explanation to be that the sense-data have an intrinsic order of their own. What this strongly suggests, the representationalist will argue, is an independent realm of objects outside our experience, having its own patterns of (mainly spatial) order, with the partial and fragmentary order of our experience resulting from our partial and intermittent perceptual contact with that larger and more stable realm.

The discussion so far provides only an initial and highly schematic picture of the representationalist's proposed explanation. It would have to be filled out in a number of ways in order to be even approximately complete. Here I will be content with three further points. First, the main focus of the discussion so far has been on *spatial* properties of material objects and the features of immediate experience that seem to suggest them. Thus the result so far is at best only a kind of skeletal picture of the material world, one that would have to be "fleshed out" in various ways in order to even approximate the common-sense picture of the world. In fact, it is useful to think of the representationalist explanation as starting with spatial properties as a first and most fundamental stage and then adding further refinements to that starting point.

Second, the most important addition to this initial spatial picture of the world would be various sorts of *causal* relations among material objects and between such objects and perceivers, together with the causal and dispositional properties of objects (flammability, solubility, malleability, brittleness, toxicity, etc., etc.) that underlie such relations. These are warranted by the need to explain apparent changes in material objects that are reflected in relatively permanent changes in the otherwise stable "sensory routes". Here it is important to note that like the stable spatial order, the causal regularities that pertain to material objects are only intermittently and fragmentarily reflected in immediate experience, partially for the reasons already considered, but also because any given perceiver may simply not be in the right position to observe the beginning or end or some intermediate part of a given causal sequence, even though other parts are experienced. Simple examples would include throwing a rock into the air without seeing or hearing it land, pulling on a string without observing the movement of an object at the other end (or seeing the object move but without observing the movement of part of the intervening string), or planting a seed and returning later to find a well-developed plant.[16]

Third, there is the issue of primary and secondary qualities. Locke's view was that material objects have *primary* qualities like size, shape, and motion through space, but not *secondary* qualities like color, smell, taste, and felt temperature; and most other representationalists have tended to agree with him on this. Here it will suffice to focus on color, surely the most apparently pervasive and interesting of the secondary qualities.[17] Clearly the denial that material objects are genuinely colored seriously complicates the representationalist's proposed explanation by making the relation between material objects and our immediate experiences much less straightforward than it would otherwise be: according to such a view, while our immediate experiences of spatial properties are caused more or less directly by closely related spatial properties of objects (allowing, importantly, for perspective), our immediate experiences of color properties are caused by utterly different properties of material objects, primarily by

how their surfaces differentially reflect wavelengths of light.

Locke offers little real argument for this view, but the argument he seems to have in mind is that as the causal account of the material world develops, it turns out that ascribing a property like color (construed as the "sensuous" property that is present in immediate visual experience) to material objects is in fact quite useless for explaining our experiences of colors. What colors we experience depends on the properties of the light that strikes our eyes and this in turn, in the most standard cases, depends on how material objects reflect and absorb light, which yet in turn depends on the structure of their surfaces as constituted by primary and causal properties. I think that this is correct as a matter of science, but the important point for the moment is that *if* it is correct, then the denial that material objects are really colored simply follows from the basic logic of the representationalist position: according to representationalism, the only justification for ascribing *any* property to the material world is that it is required to explain some aspect of our immediate experience, so that the ascription of properties that cannot figure in such explanations is automatically unjustified.

Alternatives to the Representationalist Explanation

The discussion so far has perhaps made a reasonable case, though of course nothing like a conclusive one, that the representationalist's proposed explanation of the order of our immediate experience has a good deal of plausibility in relation to that experience. But this is still not enough to show that it is the *best* explanation and hence the one, assuming the general acceptability of theoretical reasoning, whose acceptance is thereby justified. Why, if at all, should the explanation of our experience that invokes external, mind-independent material objects be preferred to other possible explanations such as Berkeley's view that our sensory experience is caused by God, who shapes and maintains the order that it reflects (or the very similar if not identical one that appeals to Descartes's evil genius)?

It should be obvious that Berkeley's explanatory hypothesis is capable of explaining the very same features of immediate experience that the representationalist appeals to. All that is needed is for God to have an ideally complete conception or picture of the representationalist's material world and then to systematically cause experiences in perceivers that reflect their apparent location in and movement through such a world. (This assumes that God can recognize intentions to "move" in various directions and adjust the person's perceptions accordingly; of course, no genuine movement really takes place, nor does the perceiver really have a physical location.) A different, but essentially parallel explanatory hypothesis, is provided by a science fiction scenario: the perceiver is a disembodied brain floating in a vat of brain nutrients and receiving electrical impulses from a computer that again contains an ideally complete model or representation of a material world and generates the impulses accordingly, taking account of motor impulses received from the brain that reflect the person's intended movements. And further explanatory hypotheses can be generated according to the same basic formula: there must be some sort of a representation or model of a material world together with some sort of mechanism (which need not be mechanical in the ordinary sense) that systematically produces experience in perceivers, allowing for their subjectively intended movements. *Any* pattern of immediate experience that can be explained by the representationalist's explanatory hypothesis can thus automatically be also explained by explanatory hypotheses of this latter sort, probably indefinitely many of them, with no possible

experiential basis for deciding between them or between any one of them and the representationalist hypothesis.

If there is to be a reason for favoring the representationalist hypothesis, it will therefore have to be *a priori* in character, and it is more than a little difficult to see what it might be. Here I will limit myself to one fairly tentative suggestion.

One striking contrast between the representationalist's explanatory hypothesis and the others we have looked at is that under the representationalist view there is a clear intuitive sense in which the qualities of the objects that explain our immediate experience are reflected in the character of that experience itself, so that the latter can be said to be, allowing for perspective and perhaps other sorts of distortion, experiences of the former, albeit indirect ones. Once again this applies most straightforwardly to spatial properties: thus, for example, the rectangular or trapezoidal shape that is immediately experienced can be said to be an indirect perception of a rectangular face of the material object that causes that experience. In contrast, the features of the elements in the other explanatory hypotheses that are responsible for the various features of our experience are not directly reflected in that experience. For example, what is responsible in these other hypotheses for the rectangular or trapezoidal shape in my immediate experience is one aspect of God's total picture or conception of a material world, or perhaps one aspect of a representation of such a world stored in a computer. This aspect has in itself no shape of any sort (or at least, in the case of the computer, none that is at all relevant to the shape that I experience); it is merely a *representation* of a related shape, according to some system of representation or coding. Thus its relation to the character of the experience that it is supposed to explain is inherently less direct, more convoluted than is the case for the representationalist's explanation.

My tentative suggestion is that the inherently less direct character of the way that these competing explanatory hypotheses account for the features of our immediate experience may yield a reason for preferring the more direct and thus in a sense simpler representationalist explanatory hypothesis, for regarding it as more likely to be true. But how, exactly?[18] The idea is that an explanatory hypothesis like Berkeley's, at least as we have construed it, depends for its explanatory success on the truth of two equally essential claims: first, the claim that a material world of the sort postulated by the representationalist *could* account for the features of our experience, for it is precisely by emulating or mimicking the action of such a world that God (or the computer) decides just what experiences to produce in us; and, second, that God (or the computer) can indeed successfully produce the required emulation. But the representationalist view requires only the truth of the first of these two claims. It is thus, I suggest, inherently less vulnerable to problems and challenges and so more likely to be true. And this is an apparent reason for regarding the representationalist's explanatory hypothesis as providing the best of these competing explanations.

Is this a successful argument for representationalism? There are at least two questions about it that need to be considered. First, the argument assumes that the competitors to representationalism are all parasitic upon the representationalist explanatory hypothesis in the way indicated, and it is worth asking whether this is really so. Is there an explanation of our immediate experience that does not in this way rely on an

emulation of the way in which a material world would produce that experience? Second, even if the argument succeeds to a degree, *how* probable or likely does it make the material world hypothesis in comparison to these others? Is the resulting degree of probability or likelihood high enough to agree approximately with our common-sense convictions in this regard?

2.3 Direct Realism

The upshot of our discussion so far is that phenomenalism appears entirely untenable, and that at least a better defense than many have supposed possible can be offered for representationalism. Many recent philosophers, however, have thought that there is a *third* alternative that is superior to either of these: one usually referred to as *direct realism*. The central idea of direct realism is that the view we have called perceptual subjectivism is false, that is, that instead of immediately experiencing either sense-data or adverbial contents, we instead *directly* experience external material objects, without the mediation of these other sorts of entities. And the suggestion often seems to be, though this is usually not explained very fully, that such a view can simply bypass the representationalist's problem of justifying the inference from immediate experience to the material world and do so without having to advocate anything as outlandish as phenomenalism.[19]

For anyone who has struggled with the idea of sense-data (or the adverbial alternative) and with the difficulties and complexities of representationalism and phenomenalism, the apparent simplicity of direct realism, the way in which it seems to make extremely difficult or even intractable problems simply vanish, may be difficult to resist. We must be cautious, however. What does such a view amount to, and can it really deliver the results that it promises?

We may begin with a point that is often advanced in arguments for direct realism, one that turns out however to be of much less help than has sometimes been thought in either defending or even explaining the view. Think about an ordinary example of perceptual experience: standing in my back yard, I watch my dogs chasing each other in a large circle around some bushes, weaving in and out of the sunshine and shadows, as a car drives by on the street. The direct realist's claim is that in such a case (assuming that I am in a normal, non-philosophical frame of mind), the picture that it is easy to find in or read into some representationalists, according to which I *first* have thoughts or occurrent beliefs about the character of my experience (whether understood in sense-datum or in adverbial content terms) and *then* infer explicitly from these to thoughts or beliefs about material objects is simply and flatly wrong as a description of my actual conscious state. In fact, the only things that I think about at all *directly* and explicitly in such a case are things like dogs and bushes and cars and sunlight, not anything as subtle and abstruse as sense-data or adverbial contents. The direct realist need not deny (though some have seemed to) that my sensory experience somehow involves the various qualities, such as complicated patterns of shape and color, that these other views have spoken of, or even that I am in *some* way aware of conscious of these. His point is that whatever may be said about these other matters, from an intuitive standpoint it is material objects and nothing else that are "directly before my mind" -- and that any view that denies this obvious truth is simply mistaken about the facts.

Almost everyone will agree that the direct realist is right about this. What happens most centrally in perceptual experience is that we have explicit thoughts or "perceptual judgments" about what we are perceiving; and in normal cases (apart from very special artistic or perhaps philosophical contexts), these perceptual judgments are directly and entirely about things (and processes and qualities) in the external material world. Philosophers speak of that which a propositional state of mind is directly about as its *intentional object*, and we can accordingly say that the intentional objects of our basic perceptual judgments are normally material objects. In this way, the relation of such judgments to material objects is, it might be said, *intentionally* direct.

But what bearing, if any, does this intentional directness have on the central epistemological question of what reason or justification we have for thinking that such perceptual judgments about the material world are *true*? *Perhaps* the sort of direct presence to the mind that is involved in the idea of immediate experience considered earlier yields the result that one's beliefs or awarenesses concerning the objects of such experience are automatically justified, simply because there is no room for error to creep in. But is there any way in which it follows from the mere fact that perceptual judgments about material objects are *intentionally* direct that they are also *justified*? It still seems obvious that both a perceptual judgment and the total state of mind of which it is a part are quite distinct from the material object, if any, that is its intentionally direct object. This is shown by the fact that in cases like hallucination, the object in question need not exist at all, but it would be clear enough even without such cases -- phenomenalist views having been rejected, the material object does not somehow literally enter the mind. Thus even though perceptual judgments are directly about such objects in the intentional sense, the question of whether they represent them correctly still arises in exactly the same way that it does for the representationalist. And this question must apparently still be answered, if at all, by appeal to the immediately experienced features of that state of mind, with the specific character of the sensory experience being the only obvious thing to appeal to.

Thus while the idea of intentional directness contributes to a view that presents a somewhat more accurate picture of the perceptual state of mind, the view that results seems to still be fundamentally a version of representationalism in that it faces the same essential problem of justifying the transition (whether it is an explicit inference or not) from the character of the person's experience to beliefs or judgments about the material world. If this is all that direct realism amounts to, then it is not a genuinely distinct third alternative.

Is there any further way to make sense of the "directness" to which direct realist appeals, one that might yield more interesting epistemological results? It is far from obvious what it would be. Some proponents of this supposed view have tried to deny that we have any awareness of the character of our immediate experience that is both distinct from our judgmental awareness of material objects and of the sort that could provide the basis for the justification of material object claims. Such a challenge raises subtle and difficult issues about different kinds of awareness, but it is hard to see how it could really be correct. Moreover, the correctness of this challenge, while it would surely constitute a serious or perhaps even conclusive objection to representationalism, would not yield in any obvious way a positive direct realist account of how beliefs about the material world are justified, if not in the representationalist way.

My tentative conclusion is that the idea that direct realism represents a further alternative on the present issue is a chimera. Thus, once phenomenalism is rejected as hopeless, the only alternatives with regard to knowledge of the external world appear to be skepticism and some version of representationalism, perhaps one that recognizes and incorporates the view that perceptual judgments about the material world are intentionally direct.

2.4 Conclusion

The following two conclusions seem to me to be fairly strongly supported by the foregoing discussion. First, some version of perceptual subjectivism is probably correct, with the adverbial theory being the more promising of the two main alternatives. Second, assuming that perceptual subjectivism is indeed correct, representationalism is by far the most defensible non-skeptical account of how beliefs concerning material objects are justified. But there are many philosophers who regard direct realism as a more promising alternative than has been suggested here. And there are perhaps many more (though not the present author) who believe that some epistemological view at a different level, such a a coherentist or contextualist theory of justification, can circumvent these problems.

3. Externalist Theories of Perception

As noted at the beginning, the foregoing discussion is entirely concerned with the views and issues that arise under an *internalist* account of epistemic justification. The adoption of an *externalist* account of justification alters and greatly simplifies the account of the justification of perceptual beliefs. Here I wll focus on the most standard version of exernalism, namely *reliabilism*, according to which a belief is justfied if it results from a reliable causal process.[20]

On such a reliabilist view, the justification of a perceptual belief depends only on the reliability of the perceptual process that produces it, that is, on the fact (*assuming that it is a fact*) that this process leads to a suitably high proportion of true beliefs. (Note that it is *not* required that the believer or anyone else know that the process is reliable or have any sort of cognitive access to its reliability -- all that is required it is that is in fact reliable.) The justification of such a belief thus requires no appeal to sensory experience at all, thus effectively short-circuiting the issue that divides representationalism and phenomenalism. Such reliabilist views might in a way be viewed as versions of direct realism, but it is less misleading to simply regard them as rejecting the issue which all three of the more traditional theories attempt to respond to: the issue of how sensory experience provides a reason for thinking that perceptual beliefs are true.

Reliabilism thus offers a very sraightforward and seemingly unproblematic account of how perceptual beliefs about physical objects and the physical world are, in a sense, justified -- again, on the assumption that our perceptual processes are in fact reliable in the way that we take them to be. But it is important to realize that even if this last assumption is correct, the reliabilist account is quite compatible with our having no reason at all for thinking that such processes are indeed reliable and so no reason at all for

thinking that our perceptual beliefs are either justified or likely to be true. It is for this reason that the ease with which the standard issues are avoided on a reliabilist view may seem to constitute a defect rather than a virtue of the position.

Notes to Epistemological Problems of Perception

Notes

1. Yet another way to refer to this same basic idea is to speak of objects with which we are acquainted (or, sometimes, directly acquainted). See Russell [1912], chapter 5.

2. For a fairly comprehensive but rather one-sided discussion of responses to the argument from illusion, see J. L. Austin [1962].

3. A further advantage often claimed for the adverbial theory is that it is compatible with materialist views of the mind: while it is clear that the brain does not contain entities having the properties ascribed to sense-data and at best obscure how it could stand in a relation of apprehension to such entities, there is no clear reason why a state of being appeared to silver-elliptical-ly could not just be a brain state. (To which it might be responded: (i) that we have no real understanding of how it could be a brain state either, of what features of a brain state would make it such a state of being appeared to; and (ii) that the absence of any clear difficulty here is simply a reflection of the obscurity of the nature of the supposed adverbial state.)

4. This term is my own coinage and not one that is generally used.

5. One major proponent of the sense-datum theory has advanced the argument that the adverbial theory cannot adequately capture all of the cases that can be described in terms of sense-data, in particular that it cannot adequately describe cases in which we experience a number of different apparent objects having a variety of different properties in a way that keeps straight which object has which property. Thus compare a case in which I am experiencing a red circle and a green square with one in which I am experiencing a green circle and a red square. In both cases, I might be said to be sensing or to be appeared to red-and-green-and-round-and-square-ly, thus apparently failing to capture the distinction between the two cases. And the suggestion is that only the sense-datum theory can successfully distinguish what is going on in such cases, by making explicit reference to each of the apparent objects. See Jackson [1977], pp. 64-68. But this objection seriously underestimates the resources available to the adverbial theory. In the cases in question, the adverbialist can say that I sense red-circle-and-green-square-ly in the first case and green-circle-and-red-square-ly in the second case, thus capturing the difference. More generally, if it is possible to capture the content of a particular immediate experience adequately in sense-datum terms, as the proponent of sense-data must agree that it is, then the adverbialist can construct a description that is equally adequate insofar as the present issue is concerned by simply making the entire sense-datum description the basis for his adverbial modifier, that is, by saying that the person is sensing or being appeared to [such and such sense-data]-ly, with the appropriate

sense-datum description going into the brackets.

6. It is harder to identify the historical sources of phenomenalism. Contrary to what is often suggested, Berkeley's "idealist" view (in Berkeley [1710] and [1713]) is not in fact in any clear way an anticipation of phenomenalism, but rather in effect a curious version of representationalism, in which our perceptual ideas constitute partial representations of the much more complete picture of the material world constituted by God's much more complete ideas. The phenomenalist view is at least suggested, but never quite arrived at in Hume [1739-40], Part IV, Sections 2-4. Perhaps the earliest reasonably clear statement is Mill [1865].

7. Or the features reflected in immediately experienced adverbial contents. But, as noted above, I will mostly leave this alternative possibility to be supplied by the reader.

8. Mill [1865].

9. There is also, as briefly mentioned earlier, a second fairly widely advocated argument for phenomenalism, one that starts from the premise that all intelligible ideas or concepts are derived by "abstraction" from immediate experience, so that we arguably could not even understand the idea of objects existing outside of that experience. If this were so, and if (as again seems obvious) we do understand the idea or concept of a physical or material object, then it would follow that this idea or concept is not about trans-experiential objects, but can only be about some feature or aspect of experience itself. The problem with this argument is that the initial premise about the derivation of concepts is far less obviously correct than is the claim that we do in fact obviously have ideas or concepts, indeed lots of them, that are about things outside immediate experience, making it far more reasonable to reject the conclusion than to accept the premise.

10. See Ayer [1946-7] for a discussion of this example.

11. Chisholm [1957], Appendix.

12. Advanced in Sellars [1963].

13. Locke [1689], Book IV, chapter 11.

14. Berkeley [1710] and [1713].

15. For a much, much more extensive discussion of this general sort of point, see Price [1950]. A very condensed summary of Price's account is offered in BonJour [2000].

16. For a good discussion of the general representationalist argument, especially with reference to the

causal regularities in the material world, see Whiteley [1959]. Whiteley, however, eventually arrives at a more extreme view according to which material objects explain our experience but cannot be known to have *any* of the properties actually manifested in that experience.

17. Locke adds solidity to the list of primary qualities. What he has in mind by this is not entirely clear, but solidity seems to be either the feeling of resistance that a rigid object produces when touched (in which case, it seems to belong with the secondary qualities) or else the causal capacity of preventing other objects from occupying the same space (in which case it is a causal property, what Locke calls a "power," and again not a primary quality on a par with the others, all of which are directly reflected in experience).

18. Sometimes philosophers appeal in such discussions to a general standard of simplicity, according to which it is just a fundamental principle that the simpler explanation is more likely to be true. The problem with this is twofold: first, the justification or rationale for the principle in question is anything but clear; and, second, the way in which it would apply to the case with which we are concerned is at least debatable, since Berkeley's explanation, for example, might be claimed to be simpler on the grounds that it invokes only one entity, albeit an extremely complicated one, rather than the many objects that make up a material world.

19. In earlier discussions of these issues, views in the general direction of direct realism were often referred to as "naïve realism" and ascribed to unsophisticated common sense.

20. The classic presentation of externalist reliabilism is Goldman [1986]. See also Dretske [1981] and, for an earlier version of the same general approach with more explicit consideration of perception, Dretske [1969].

Interpretation and Coherence in Legal Reasoning

The subject of legal reasoning appears to occupy the more practical end of the spectrum of jurisprudential theorising. Surely if anything matters in our attempts to understand law, it matters how judges do and/or should decide cases, and that we have an account which adequately explains and can perhaps be used to guide their activities. The recent history of legal philosophy abounds with many and various attempts to address these issues and others which have been viewed as falling within the ambit of legal reasoning. Is legal reasoning an activity which is exclusive to the adjudicative institutions of legal systems or is any reasoning about the law to be regarded as legal reasoning, no matter where or by whom it is undertaken? Does legal reasoning take on a special character when it is undertaken in courts and by judges? Are there special methods or modes of reasoning which are unique to or at least distinctive of the law, or is legal reasoning just like reasoning in any other sphere of human activity, distinctive only in the subject matter to which it is applied? This last question is particularly relevant to present concerns, as it is one task of this entry to discuss various views concerning whether and to what extent interpretation and coherence have a special role to play in legal reasoning, because of the nature of law itself.

After a brief clarificatory consideration of the ambit of the term, ‘legal reasoning’, the entry deals first with interpretation and then with coherence, and discusses various views concerning these concepts and their relevance for law. Throughout, the discussion focuses upon the role which interpretation and coherence play within legal reasoning, and the reasons why these concepts are regarded by some as being distinctive of reasoning about the law.

What Do Legal Theorists Mean By 'Legal Reasoning'?

This may seem like an easy question, for surely legal reasoning is simply reasoning about the law, or about how judges should decide cases. On closer inspection, however, our ease may evaporate, for both of these formulations are ambiguous, at least according to some ways of thinking about the law. Some legal theorists regard the questions, 'what is the law?', and 'how should judges decide cases?' as distinct questions with distinct answers (see e.g. Hart 1994; Kelsen 1967; Raz 1979 & 1994). That is to say, their accounts of law and their accounts of adjudication are not one and the same, and they contend that in settling disputes which come before them, the remit of judges is wider than merely trying to establish what the law is as regards the issues in the case at hand. In adjudication, such theorists claim, extra-legal considerations can come into play, and judges may have discretion to modify existing law or to fill in gaps where existing law is indeterminate. This being so, for some legal theorists, the first formulation above, that legal reasoning is reasoning about the law, is ambiguous between: (a) reasoning to establish the content of the law as it presently exists, and (b) reasoning from that content to the decision which a court should reach in a case which comes before it.

Moreover, the second formulation of the ambit of legal reasoning given above, i.e. that legal reasoning is about how judges should decide cases, is also ambiguous on some approaches to legal theory. This is because the answer to the question, "how should a court decide a case, reasoning from the existing law applicable to it?" (i.e. legal reasoning in the sense given in (b) above) and the answer to the question, "how should a court decide a case, all things considered?", may sometimes come apart. A particular instance might be the kind of situation which could arise for a judge in a 'wicked' legal system where the law on some issue is so morally odious that, all things considered, the judge should not decide the case according to the law at all, but rather should refuse to apply the law (see Hart 1958; Hart 1994, chapter 9, section 3; Raz 1994, essay 14. This possibility is also noted by Dworkin 1986, chapter 3, 101-108, in discussing whether the Nazis had law).

There are thus three things (at least, there may be others) which legal theorists could mean by legal reasoning: (a) reasoning to establish the existing content of the law on a given issue, (b) reasoning from the existing content of the law to the decision which a court should reach in a case involving that issue which comes before it, and (c) reasoning about the decision which a court should reach in a case, all things considered.

It should be noted that some legal theorists, most notably for present purposes Ronald Dworkin, do not carve up the questions and issues on this topic in the way outlined above. For Dworkin, when judges decide a case according to law, they do no more than ascertain the content of the law and apply it to the facts of the case. In other words, judges never resort to extra-legal considerations in deciding cases according to law: all the considerations which they are entitled to take into account are part of the law. This means that, according to Dworkin, when judges reason about the law in sense (b), what they are doing amounts to no more nor less than reasoning about the law in sense (a), i.e. reasoning to establish the content of the law (see Dworkin 1977 & 1986).

This entry is concerned with legal reasoning in senses (a) and (b), and with sense (b) in particular. It should be noted that the discussion does not directly address the different accounts of the nature and limits of law which are revealed by those varying views mentioned above regarding what it is that judges do when they reason about the law in sense (b). Where such differences have a bearing upon issues pertaining to the role of interpretation and coherence in legal reasoning, they will be mentioned in the text. For further discussion of the nature and limits of law, see various entries under *nature of law* in this volume.

2. The Role of Interpretation in Legal Reasoning:

2.1 Some Intellectual Roots Considered

Recent interest in the role of interpretation in legal reasoning springs from several sources. For some, interpretation is where we should look in order to find the solution, or at least the only possible response, to the problem of linguistic indeterminacy in law which they perceive (in turn, renewed interest in the problems of linguistic indeterminacy in law seems to have stemmed at least in part from the resurgence in the last twenty years in scholarship addressing Wittgenstein's remarks on rule-following in the Philosophical Investigations (see e.g. Holtzman & Leich (eds.) 1981; Kripke 1982; Baker & Hacker, 1984 & 1985), and the migration of these concerns from philosophy of language into philosophy of law (see e.g. Marmor 1992; Stone 1995; Smith 1990). Certain aspects of this trend, most notably that of academic lawyers employing ill-digested Wittgenstein to dubious ends, are criticised by Bix 1993). According to this line of thinking, if words, and legal rules composed of words, have no intrinsic meaning and hence cannot, in and of themselves, constrain legal reasoning, then it must be we -- readers or interpreters -- who supply such meaning via the process of interpretation (see Fish 1989; Cornell 1992. Stone 1995 criticises this understanding of the role of interpretation in legal reasoning, but notes its adoption by various legal theorists). In the case of other theorists, interest in this topic stems from a wish to investigate the parallels and divergences between interpretation in law and interpretation in literature (Levinson 1982; Dworkin 1985; Fish 1989). The arrival on the jurisprudential scene in the mid-1980s of Ronald Dworkin's powerful new account of law as an interpretive concept, with concomitant implications for the activities of both judges and legal theorists (see Dworkin 1986) also did much to contribute to interest in the role of interpretation in legal reasoning. Moreover, this account seemed to rouse Dworkin's legal positivist adversaries into elaborating more fully upon something which he has

always claimed has been seriously underdeveloped in their work (see e.g. Dworkin 1977), namely an account of the nature of adjudication, and of the role of interpretation within it (Marmor 1992; Raz 1995; Raz 1996a & 1996b).

2.2 An Initial View of the Nature of Interpretation: Conservation and Creativity

As might be expected, as a result of these different (although often intertwining) intellectual backgrounds and sources of interest in interpretation, legal theorists approach this subject with very different questions and concerns to which they give concomitantly different answers. For all this, however, a surprising number of legal theorists agree -- at least at an abstract level -- about one central characteristic of interpretation, namely that interpretation is a Janus-faced concept, encompassing both a backward-looking conserving component, and a forward-looking creative one. In other words, an interpretation of something is an interpretation of *something* -- it presupposes that there is a something, or an original, there to be interpreted, and to which any valid interpretation must be faithful to some extent, thus differentiating interpretation from pure invention -- but it is also an *interpretation* of something, i.e. an attempt not merely to reproduce but to make something of or bring something out of an original. (See e.g. Fiss 1982; Dworkin 1986; Marmor 1992; Endicott 1994; Raz 1996b & 1996c.)

Much jurisprudential writing on interpretation in legal reasoning is concerned with how to strike the right balance between the conserving and creative elements in interpretation, and with the constraints which are and/or should be operative upon judges as they undertake this balancing act. Some theorists claim that such concerns about how one ought to interpret the law indicate that it is part of the way that we think about this practice that we regard rival interpretations as subject to objective evaluation as good or bad, better or worse, correct or incorrect (Dworkin 1986; Raz 1996b and 1996c). On this view, characterisations of interpretation which attempt to impugn the objectivity of such evaluations (e.g. Levinson 1982) are to be understood as revisionist accounts which attempt to persuade us that all is not as it appears to be with our practice of judging interpretations to be good or bad, better or worse, correct or incorrect as we currently understand it (see e.g. Raz 1996b).

2.3 Locating Interpretation in Legal Reasoning

It is important to consider how interpretation, as characterised in subsection 2.2 above, fits into the discussion of the ambit of the term legal reasoning in the opening section of this entry. The key to this issue lies in interpretation’s dualistic nature, i.e. that it has both a backward-looking conserving aspect and a forward-looking creative one. This dualism would seem to indicate that in interpreting the law, judges both seek to capture and be faithful to the content of the law as it currently exists, and to supplement, modify, or bring out something new in the law, in the course of reasoning from the content of the law to a decision in a particular case. In turn, this would seem to indicate that interpretation, because of its dualistic nature, has a role to play in both legal reasoning in sense (a), i.e. reasoning to establish the existing content of the law on a given issue, and legal reasoning in sense (b), namely reasoning from the existing content of the law to the decision which a court should reach in a case

involving that issue which comes before it.

One legal theorist who adopts exactly this approach, and so views interpretation in legal reasoning as ‘straddling the divide’ between identifying existing law, and developing and modifying the law, is Joseph Raz (see Raz 1996a and 1996b). According to Raz, the fact that interpretation has a role to play in both of these activities assists in explaining why we do not find a two-stage or clearly bifurcated approach to legal reasoning in judicial decisions. Judges do not first of all engage in legal reasoning in sense (a), having recourse only to legal materials, and then, having established what the existing law is and determined how far it can take them in resolving the instant case, then move on to a separate stage of legal reasoning in sense (b) which requires them to look to extra-legal materials in order to complete the job, because much of their reasoning is interpretive and interpretation straddles the divide between legal reasoning in senses (a) and (b). This point may assist Raz in defusing some of the criticisms which have been levelled at the legal positivist approach to legal reasoning such as that positivism’s account is phenomenologically inaccurate because when we examine cases, we do not find two distinct stages to judicial reasoning, one to establish whether any legal rules bear upon the problem at hand, and one wherein judges effectively legislate to fill in the gaps when the legal rules ‘run out’ (see e.g. Dworkin 1977 & 1986). As Raz himself notes, however (especially in Raz 1996b), this ‘straddling the divide’ approach may in fact seem to undermine the very ideas that there is a tenable distinction between legal reasoning in senses (a) and (b), and that there are gaps in the law. Interpretation appears to blur or even erase the line between the separate law-finding and law-creating roles which many legal positivists ascribe to judges, and the fact that courts always seem to be able to decide cases by interpreting the law may also seem to cast doubt on the idea that the law is incomplete, and hence that judges sometimes have to reach outside of the law in the adjudication process. Interest in the pervasiveness of interpretation in legal reasoning, and in the Janus-faced nature of interpretation may thus form part of the background which has led legal theorists like Dworkin to deny that the distinction between identifying existing law, and developing and changing the law, as understood by certain legal positivists, is a tenable or coherent one. That interpretation appears to operate at every stage in the legal reasoning process may also have influenced Dworkin’s denial that there are gaps in the law, and his counter-claim, contra Hart and Raz, that everything which a judge is entitled to rely on in deciding a case is already part of the law (see Dworkin 1986).

2.4 Some Points of Disagreement

Legal theorists disagree about the proper characterisation of many aspects of the schematic account of the interpretive process given in subsections 2.2 and 2.3 above. A few of these disagreements will be surveyed here in order to give a fuller picture of some of the issues and views which are relevant to this topic. Accounts of the role of interpretation in legal reasoning, then, differ regarding the following matters (n.b. several of the following points overlap to some extent):

(1) What exactly is the original or object which is being interpreted in the case of law: the law as a whole?; certain aspects of legal practice?; statutes?; judicial decisions?; authoritative legal decisions?; legal texts? Raz 1996b claims that the primary objects of interpretation are the decisions of legal authorities. He reaches this conclusion as a result of his view that law is an institutionalised normative

system wherein the institutions concerned operate by issuing purportedly authoritative directives concerning what ought to be done. According to Raz, then, the central role which authority plays in law means that when we come to interpret the law, what we are primarily seeking to do is to establish the existence and meaning of any purportedly authoritative directives of legal institutions, and it is, therefore, the decisions of those institutions which constitute the originals to be interpreted in the case of law. (See further the discussion of Raz's views in subsection 2.5 below). This stance can be contrasted with that adopted by Ronald Dworkin. The process of 'constructive interpretation' (Dworkin 1986, and see also the entry interpretivist theories of law) which plays such a central role in Dworkin's jurisprudential thought involves interpreters, 'imposing purpose on an object or practice in order to make of it the best possible example of the form or genre to which it is taken to belong.' (Dworkin 1986, p52). Moreover, in the case of legal interpretation, Dworkin appears to settle for the argumentative social practice of law as the original to be interpreted (Dworkin 1986, p63). This being so, for Dworkin, the object of legal interpretation appears to be broader than that adopted by Raz. For Raz, we interpret in order to establish whether any authoritative legal directives are currently in force and bear upon the legal issue at hand, and so we should look to the decisions establishing those directives in getting the interpretive process off the ground. Dworkinian interpretation, however, seems to have a more abstract and global feel to it, in the sense that it is the social practice of law as a whole (Dworkin 1986, 87-88), including the entire legal history of a given jurisdiction, as well as any data speaking to the point or purpose of legal practice in general, which constitutes the original to be interpreted.

(2) How much emphasis is to be placed on the conserving vs. the creative elements in interpretation? At the conserving extreme, we find accounts such as 'originalism' in US constitutional interpretation which claims that in interpreting a particular provision of the Constitution, judges should seek to establish the way in which the provision was originally understood by those who ratified it (see e.g. Bork 1990). As close as possible conformity with those original intentions thus furnishes us with the standard of correctness in constitutional interpretation on this approach. According to Bork 1990, adherence to originalism in US constitutional interpretation is necessary to ensure that the judiciary confines itself to its proper sphere of authority, thus preserving the separation of powers and structure of government in the form in which the founders of the US intended. Accounts such as that offered by Levinson (1982) reject originalism and give far more weight to the role of innovation in legal interpretation. Indeed, Levinson contends that all US constitutional interpretation is necessarily creative, due to radical and pervasive linguistic indeterminacy in the law. If such approaches wish to claim that there are standards by which we can judge interpretations to be better or worse, correct or incorrect, then they must find such standards other than in the conserving aspect of interpretation, as the requirement that one be faithful to the meaning of an original seems to be obliterated on such views. As was noted at the end of subsection 2.2 above, some such views may wish to claim that our practice of accounting interpretations as good or bad, correct or incorrect is incoherent. One other possibility, however, is that the notion of 'correctness' can be salvaged by being pegged to the communal reactions of the relevant interpretive community; our interpretations are the right ones when they accord sufficiently with those of our similarly situated fellow interpreters (see e.g. Kripke 1982 and those works discussed in point **(3)** below). Some commentators have poured scorn on the idea that this sort of approach could yield standards of correctness worthy of the name. See for example Baker & Hacker 1984, who contend that Kripke's position amounts to the view that, 'an unjustified stab in the dark is unobjectionable as long as it is made in good company.' (Baker

and Hacker 1982, 81-82).

(3) Following on from point **(2)** above: how big a role does the requirement that judges must be faithful to an original play in constraining legal interpretation, and are there any additional constraints which supplement the constraints generated by the need to be faithful to an original which guide judges as they interpret the law? For example, for Owen Fiss (1982), ‘disciplining rules’ in the form of those standards which are constitutive of the profession of judging supply constraints upon judicial interpretation which supplement the rules of language which already constrain all language users in their attempts to understand texts. According to Fiss, then, judges are constrained both by the need to be faithful to the original legal text which they are interpreting, and by supplementary norms of interpretation which are constitutive of the judicial role (Fiss lists the requirement that judges must always consult history when interpreting the law as an example of a ‘disciplining rule’). Fiss’ view is criticised by Stanley Fish (1989), who contends that Fiss’ ‘disciplining rules’ would themselves require interpretation in order for judges to know what they mean and require of them, and hence cannot supply constraints upon judicial interpretation. Fish’s contention that all potential candidates which might constrain interpretation are themselves susceptible to being interpreted in a variety of ways results in his claiming that texts or originals cannot constrain judges at all in the way in which is commonly supposed, as texts do not have meanings in advance of particular interpretations of them. This seemingly radical indeterminacy is deceptive, however, for although Fish removes the constraints on interpretation provided by legal texts or supplementary norms of the judicial profession, he replaces them with the conditioning and training processes of ‘interpretive communities’, which ensure that, ‘...readers are already and always thinking within the norms, standards, criteria of evidence, purposes and goals of a shared enterprise’, such that, ‘the meanings available to them have been preselected by their professional training.’ (Fish 1989, 133).

(4) Whether or not it is possible to have a general *theory* of interpretation. Raz 1996a rejects the possibility of two types of general theories of interpretation: ‘operational’ or recipe-like theories which are designed to guide judges to the right decision in a case which comes before them, and theories which, although they may not aim to guide judges to the correct decision, nonetheless claim to provide us with criteria via which to distinguish good interpretations from bad, and so enable us to check the correctness of decisions which have been made. According to Raz, theories of the former kind are impossible because morality (to which recourse must be had as regards the innovative aspect of legal interpretation) is not susceptible to explanation via ‘operational’ theories, i.e., ‘theories which would enable a person whose moral understanding and judgement are suspect to come to the right moral conclusions regarding situations he may face by consulting the theory.’ (Raz 1996a, p21. In this he follows similar claims made by several contemporary moral philosophers, e.g. Williams 1985; Dancy 1993). Moreover, claims Raz, theories which purport to tell us how to differentiate good interpretations from bad are also impossible because, by its very nature, innovation defies generalisation, such that it is futile to attempt to construct a general theory which differentiates good interpretations from bad as regards the forward-looking aspect of interpretation. It should be noted that (as is apparent from the discussions in this entry as a whole), Raz does believe that it is possible to have an account which explains certain aspects of the nature and role of interpretation in legal reasoning; what he doubts is that it is possible to have a certain kind of account of interpretation, namely an account in the form of a theory which purports either to operate as a recipe for concocting good interpretations, or to provide us with a general account of how to evaluate interpretations

as good or bad, right or wrong.

Ronald Dworkin, by contrast, does purport to offer judges a general theory of legal interpretation which they can use to guide their interpretive activities, and which, if followed correctly, will lead them to the 'one right answer' in the case before them (on Dworkin's 'one right answer' thesis, see further point **(7)** below). For Dworkin, it is the aim of all legal interpretation to 'constructively interpret' the social practice of law, by imposing purpose upon it such as, 'to make of it the best possible example of the form or genre to which it is taken to belong.' (Dworkin 1986, p52). The more specific theory which he believes that judges should follow in fulfilling this task -- 'law as integrity' -- 'instructs judges to identify legal rights and duties, so far as possible, on the assumption that they were created by a single author -- the community personified' (see subsections 2.5 and 3.4, and the entry [interpretivist theories of law]). It should be noted, however, that while Dworkin's general theory of interpretation is designed to assist in guiding judges to the one right answer in a case which comes before them, he claims that it is not recipe-like in the sense of providing judges with a detailed step by step programme for correct judicial decision-making: 'I have not devised an algorithm for the courtroom. No electronic magician could design from my arguments a computer program that would supply a verdict everyone would accept once the facts of the case and the text of all past statutes and judicial decisions were put at the computer's disposal' (Dworkin 1986, p. 412).

Dworkin's pro-theory stance has attracted criticism from a variety of quarters. Fish (1989, essays 4, 5 and 16) claims that 'law as integrity' is not a theory which judges can use to guide their interpretive activities because it is a strategy which they cannot help but put into practice, and to which they are always and already committed simply in virtue of their membership in the judicial interpretive community. Sunstein 1996 also warns against the kind of 'high-level theories' which Dworkin instructs judges to construct and follow in deciding cases. Sunstein is suspicious of the value of such theorising on the grounds that, 'it takes too much time and may be unnecessary; because it may go wrong insofar as it operates without close reference to actual cases; because it often prevents people from getting along at all; and because general theorizing can seem or be disrespectful insofar as it forces people to contend, unnecessarily, over their deepest and most defining moral commitments.' (Sunstein 1996, p50). Instead, Sunstein advocates a special role for 'incompletely theorized agreements' in judicial decision-making. Such agreements can occur where judges agree on the outcomes of individual cases even though they disagree on which general theory best accounts for those outcomes, or agree on a general principle, but not on what that principle requires in particular cases, or agree on a 'mid-level' principle (see Sunstein 1996, p36) but disagree about both the general theory underlying it and particular cases falling under it. Sunstein regards incompletely theorised agreements as vital to legal reasoning, because they allow the diverse individuals who constitute the judiciary to agree on outcomes against the background of certain institutional constraints such as that they have, 'a weak democratic pedigree and limited fact-finding capacity' (Sunstein 1996, p6), must make many decisions, make them fairly quickly, show adequate respect, to litigants, and to each other, and avoid error insofar as is possible. Sunstein presents a strong case for the role of incompletely theorised agreements in law in general, pointing out that the institution of such agreements is one of the most important social functions of legal rules, as rules are capable of allowing agreement in the face of disagreement, in the sense that sometimes judges can agree on outcomes to cases governed by a rule whilst disagreeing about the rule's justification (on this important function of legal

rules see also Raz 2001).

(5) Whether or not interpretation is always of something which to some extent already has meaning, or whether interpretation is the *fundamental* determinant of the meaning of linguistic expressions in, for example, legal texts. Marmor 1992 & Stone 1995 deny that interpretation is the fundamental determinant of the meaning of linguistic expressions and contend that, following a certain reading of Wittgenstein's remarks on rule-following (namely the kind of reading offered by McDowell 1984 and Baker and Hacker 1985), it must be possible for us to grasp the meaning of, for example, a legal rule, in a way which does not require recourse to interpretation. Cornell 1992 & Fish 1989 deny this, and contend that interpretation is all-pervasive, and is the fundamental and inescapable determinant of meaning, 'all the way down', in all cases. In the minds of some legal theorists at least, this point has strong links with with the issue of linguistic indeterminacy in law mentioned in subsection 2.1 above (see e.g. Fish 1989; Cornell 1992). Those theorists who contend that interpretation is the fundamental determinant of the meaning of linguistic expressions often claim that such interpretation is necessary because legal rules expressed in language do not have determinate meanings and hence cannot determine their own correct application; in John McDowell's terminology, those rules, by themselves, cannot have 'normative reach.' (McDowell 1984 & 1992). This being the case, so this line of thinking goes, interpretation is required in order to bridge the gap between the inert legal rule and the situations to which it applies. For these theorists, the pertinent issue then becomes: how do we know that one interpretation rather than another is in accordance with the rule, if the rule itself cannot determine its own correct application? As Wittgenstein notes in his remarks on rule-following, it seems that: ' 'Whatever I do is, on some interpretation, in accord with the rule'', such that we can, '...give one interpretation after another; as if each one contented us at least for a moment, until we thought of yet another standing behind it.' (Wittgenstein 1967, §198 and §201 respectively). Some theorists, e.g. Fish 1989, seem to embrace this potential infinite regress of alternative interpretations of rules (see also point **(3)** above) and attempt to avoid the radical linguistic indeterminacy which it seems to entail by replacing the standards of correctness demarcated by rules with the conditioning and training processes of interpretive communities. For theorists like Marmor (1992) and Stone (1995) who deny that interpretation is the fundamental determinant of the meaning of linguistic expressions, the Wittgensteinian challenge is seen as a kind of *reductio ad absurdum* which indicates that we have gone astray in our understanding of how rules operate. Such theorists seek to avoid linguistic indeterminacy, and reject interpretation as the fundamental determinant of meaning by denying that there is a gap which needs to be bridged between grasping a rule and understanding those actions which it requires. As was noted above, this denial usually proceeds via a non-sceptical reading of Wittgenstein's remarks on rule-following, along the lines of that offered by McDowell 1984 and Baker and Hacker 1985.

(6) Which values judges should attempt to realise in legal interpretation, and how those values are to be balanced against one another. One debate on this issue is that between Dworkin (1986), who champions the role of the value of integrity in interpreting the law, and those who, like Raz (1994a), and Réaume (1989), doubt whether Dworkinian integrity *is* a value which should be pursued in legal interpretation. The value of coherence in legal reasoning is addressed further in Section 3 of this entry.

(7) Whether interpretation in legal reasoning can lead judges to the 'one right answer' as regards the legal issue at hand. For example, Finnis 1987 denies that it is possible for interpretation in legal reasoning to

lead judges to one right answer in the sense claimed in Dworkin 1986, because of pervasive incommensurabilities in the criteria by reference to which we are supposed to adjudge one interpretation to be better than another. Finnis argues, *contra* Dworkin, that while we should seek good answers and avoid bad ones, we should not delude ourselves into dreaming of uniquely correct answers to issues of legal interpretation, for to do so commits us to, ‘utilitarianism’s deepest and most flawed assumption: the assumption of the commensurability of basic goods and thus of the states of affairs which instantiate them.’ (Finnis 1987, p. 375). Dworkin (1986 & 1991) remains firmly committed to the one right answer thesis, although it should be noted that in Dworkin 1986 chapter 11 he makes the point that in a sense there can be different ‘right answers’ for different interpreters: ‘For every route that Hercules took from that general conception to a particular verdict, another lawyer or judge who began in the same conception would find a different route and end in a different place, as several of the judges in our sample cases did. He would end differently because he would take leave of Hercules, following his own lights, at some branching point sooner or later in the argument.’ (Dworkin, 1986, p. 412).

2.5 Interpretation: Desirable or Necessary? or Why Is Legal Reasoning Interpretive?

The points of disagreement surveyed above speak to differing views regarding how judges should go about interpreting the law, and how we should understand their activities. Such concerns, however, do not directly address the important question of whether there is something about the nature of law which makes it either desirable or necessary that interpretation should play a role in legal reasoning in the first place. In other words: why is legal reasoning interpretive at all?

Raz 1996c contends that while some conventions of legal interpretation vary according to time and place, there are other features which legal interpretation necessarily exhibits, owing to the nature of law itself. While we can debate about the desirability of conventions of interpretation falling into the former category (e.g. we can consider the value of allowing the work of legal academics, or records of Parliamentary debates to serve as aids to interpretation in a particular jurisdiction), the latter category of features leave us no room for manoeuvre: courts cannot help but have recourse to them in interpreting the law. According to Raz, assigning a limited role to the intentions of legislators in the interpretation of legislation is one such necessary feature of legal interpretation. It is, he claims, simply part of our way of thinking about legislative institutions that their procedures and modes of operation are designed so as to allow legislators to make the law which they intend to make. To assume otherwise, Raz contends, is to render unintelligible any possible justification for entrusting law-making powers to those institutions. This being so, when judges come to interpret the decisions of legislative institutions, they must do so such that the law thus interpreted reflects the intentions of those who made it.

These considerations may also seem to speak mainly to the issue of how we are to go about interpreting aspects of the law. However, the reasons why it is important to pay attention to the intentions of law-making institutions when we interpret the law also furnish us with Raz’s answer to the question of why legal reasoning is interpretive at all. We pay attention to the intentions of law-making institutions because it is important to establish which legal rules those institutions have laid down, and what they mean. In

turn, it is important to establish the existence and meaning of legal rules laid down by law-making institutions because of law's purportedly authoritative nature. For Raz, legal institutions claim to express binding and authoritative judgements regarding what ought to be done which are designed to allow people to better conform to reason if they follow the decisions of the authority than if they try to follow those other reasons which apply to them directly (see Raz 1994, ch.10). In deciding cases according to law, then, we have a responsibility to try to establish the existence and meaning of any purportedly authoritatively binding legal rules which have a bearing on the situation under consideration, and we do so by interpreting the decisions of law-making institutions in a way which accords with the intentions of those institutions in making the decisions in question. For Raz, then, it is the authoritative nature of law which explains why legal reasoning is interpretive, whereas, for example, moral reasoning is not. Law, unlike morality, stems from social sources (on the role of social sources in understanding law, see Raz 1979 and the entry on legal positivism), from institutions issuing purportedly authoritative directives which claim to express a binding judgement about what ought to be done. Part of our task in reasoning about the law is thus to establish the existence and meaning of those directives, and, in order to do so, we must interpret the decisions of law-making institutions in accordance with the intentions of the law-makers in order to try to establish the content and meaning of the law which they intended to make (see also Raz 1996a and 1996b).

It is interesting to compare Raz's stance on the reasons why legal reasoning is necessarily interpretive with Ronald Dworkin's views on this topic. Rather than being based on the view that in ascertaining the content and meaning of the law, we should look to authoritative social sources, Dworkin's contention that legal reasoning is necessarily interpretive rests on an account of law which expressly repudiates the Razian understanding of law as source-based. According to Dworkin, the view that law is to be identified by reference to authoritative social sources yields a grossly inadequate account of the argumentative nature of legal practice, and of the nature and depth of disagreement within it (see Dworkin 1986 ch.1). He contends that an adequate account of these features of legal practice can only be gained when we understand that law is an interpretive concept, i.e. that it is a social practice wherein a certain interpretive attitude has taken hold. The attitude in question comprises two components: the assumption that the practice does not merely exist, but has a purpose or point, and the further assumption that the rules of the practice are not necessarily what they have always been taken to be, but rather are sensitive to, and can be revised in light of, its point (Dworkin 1986 ch.2). For Dworkin, then, it is these features of the social practice of law: that members of that practice dispute and disagree about what the best interpretation of the rules of the practice are, in light of its point, which dictate that legal reasoning is necessarily interpretive. Once the interpretive attitude has taken hold amongst the participants in a social practice, the only way to understand it adequately is to do as the participants in that practice do: i.e. join the practice and make the same kind of interpretive claims concerning the point of the practice, and what the rules of it are in light of that point, as they do. For Dworkin, this point holds good for the activities of judges and legal theorists alike: anyone reasoning about the law is required to treat it as an interpretive social practice and offer interpretations of what it requires in light of the purpose or point which they assign to it.

3. The Role of Coherence in Legal Reasoning:

As several commentators have noted (see Kress 1984; Marmor 1992; Raz 1994a), coherence theories, long influential in other areas of philosophy (see, for example, the entries on the coherence theory of truth and coherentist theories of epistemic justification) have more recently found their way into the philosophy of law. While this migration may be attributed in part to the frequent influence of the general philosophical climate upon the intellectual weather systems of jurisprudential theorising, it also makes sense to ask whether there is something about the nature of law which makes it particularly ripe for explanation via coherence accounts. For example, those commentators who view Ronald Dworkin's theory of law as integrity as a coherence account appear to answer this question in the affirmative (see e.g. Kress 1984; Hurley 1989): coherence, in the sense of interpreting the law as speaking with one voice as integrity requires, is a value which is supposed to have special relevance in the legal realm, in terms of the role which it should play in guiding judges seeking to interpret the law correctly. It has also been noted that features of the law such as the doctrine of precedent, arguments from analogy, and the requirement that like cases be treated alike seem particularly apt to be illuminated via some kind of coherence explanation. (See Kress 1984. Raz 1994a notes the temptation here, but contends that there is nothing inherent in arguments from analogy or in the requirement that like cases be treated alike which demands that they be understood in terms of a coherence account of adjudication. See also the entry precedent and analogy in legal reasoning.) Moreover, the idea of coherence as a special virtue of interpretation in legal reasoning plays an important role in the work of several major continental legal philosophers (see e.g. Peczenik 1989; Alexy 1989; Aarnio 1987; Alexy & Peczenik 1990).

The following discussion attempts to explore some of these issues concerning whether and why considerations of coherence have an important role to play in understanding law. As this entry seeks to illuminate the role of coherence in legal reasoning, the emphasis here is on coherence accounts of adjudication, and on examining the role which coherence plays in courts' reasoning about how to decide cases according to law. This being so, this part of the entry discusses legal reasoning in the sense outlined in formulation (b) in Section 1 ("What Do Legal Theorists Mean By 'Legal Reasoning'?"), i.e. reasoning from the content of the existing law on a given issue to the decision which a court should reach in a case involving that issue which comes before it.

3.1 What Constitutes Coherence?

Two central questions must be addressed in considering the role of coherence in legal reasoning: what is the nature of the coherence relation which features in coherence accounts of adjudication, and what role does coherence play in explaining or justifying judicial decisions in such accounts?

Amongst those legal theorists taking an interest in the role of coherence in legal reasoning, there is general agreement both that the coherence in question must amount to more than logical consistency amongst propositions (see Kress 1984; MacCormick 1984; Marmor 1992; Alexy & Peczenik 1990) and that it is not clear from many coherence accounts exactly what this something more amounts to (see Kress 1984; Peczenik 1989; Marmor 1992). MacCormick 1984 views coherence in terms of unity of principle in a legal system, contending that the coherence of a set of legal norms consists in their being related either in virtue of being the realisation of some common value or values, or in virtue of fulfilling some

common principle or principles. Raz 1994a also characterises coherence in law in terms of unity of principle. On his view, the more unified the set of principles underlying those court decisions and legislative acts which make up the law, the more coherent law is.

Other writers have attempted to supply a more formal definition of, for example, a minimally coherent legal system (see Levenbook 1984), or otherwise to flesh out in a more detailed manner the criteria of coherence. Alexy and Peczenik 1990 define coherence in terms of the degree of approximation to a perfect supportive structure exhibited by a set of propositions, and list ten criteria by reference to which coherence thus defined can be evaluated (the criteria are: (1) the number of supportive relations, (2) the length of the supportive chains, (3) the strength of the support, (4) the connections between supportive chains, (5) priority orders between reasons, (6) reciprocal justification, (7) generality, (8) conceptual cross-connections, (9) number of cases a theory covers, and (10) diversity of fields of life to which the theory is applicable). Such an approach raises many questions, such as how these various criteria of coherence are to be weighed and balanced against each other, and whether it is always the case that the weighing operation will result in a complete ranking of given sets of propositions as either more or less coherent than each other, so that when faced with competing such sets, it is always possible to find the most coherent set of propositions according to the ten criteria. Alexy and Peczenik recognise that weighing and balancing the criteria of coherence will be a complex matter, but appear to assume that it will always be possible to establish which is the most coherent of rival sets of propositions.

A further characterisation of the kind of coherence which is to be sought in legal reasoning may be found in Ronald Dworkin's work. Many writers regard Dworkin's account of integrity in adjudication as an example of a coherence account. (See Hurley 1989 & 1990; Marmor 1992. Kress 1984, although writing before Dworkin had fully developed his account of law as integrity, also views Dworkin as offering a coherence account of adjudication. Raz 1994a disputes the idea that Dworkin's account of law should be understood as a coherence account.) On this view, judges should try to realise the value of coherence in judicial decisions by interpreting the law as 'speaking with one voice', i.e. they should identify legal rights and duties on the basis that they were all created by a single author, the community personified.

3.2 Coherence of What?

The next issues to consider are (1) what is to be made coherent in coherence accounts of legal reasoning, and (2) what role coherence plays in explaining or justifying judicial decisions on such accounts. Regarding the question of what is to be made coherent in coherence accounts of legal reasoning, Raz 1994a contends that coherence accounts, when applied to law, require a 'base' or something which is to be made coherent, which differs in character in some crucial respects from the sort of base which features in coherence accounts in other areas of philosophy. Raz points out that while coherence accounts of justified belief take each person's belief set as their 'base' or as that which is to be made coherent, coherence accounts of law cannot be person-relative in this way, on pain of failing to offer an account which is in touch with the concrete reality of law in the jurisdiction under consideration. Raz's contention is that the law of a given jurisdiction does not vary with the beliefs of those subject to it, and in his view, that law is objective in this way means that there must be a common base to which coherence accounts in law are addressed. His suggestion in this regard is that coherence accounts in law take court decisions and

legislative and regulatory acts as their base, and hold law to be the set of principles that makes the most coherent sense of that base. Raz further distinguishes between coherence accounts of law and coherence accounts of adjudication. The essential difference between them is the stage at which considerations of coherence come into play. In the case of a coherence account of law, the whole of what the law *is* is determined by applying a coherence test to those court decisions and legislative and regulatory acts of a given jurisdiction. A coherence account of adjudication, however, accepts that the vagaries of politics and the influence of political considerations on legislative and judicial decisions make it unlikely that the settled law of a jurisdiction will exhibit coherence to any great extent. This being so, if we are to apply a coherence account in order to determine how judges ought to decide cases according to law (legal reasoning in sense (b)), then we should assume a coherence-independent test to identify the settled law of a jurisdiction first, and then bring in considerations of coherence at a later stage, and hold that courts ought to adopt that outcome to a case which is favoured by the most coherent set of propositions which, were the settled rules of the system justified, would justify them.

MacCormick 1984 espouses a similar view of the role which coherence can play in adjudication and gives an indication of how we might think of the links between interpretation and coherence in legal reasoning. According to MacCormick, in deciding a case according to law, courts should first of all interpret the existing law in order to establish a coherent view of some branch of the law, and they should do this by showing how that branch of law is justified according to some coherent set of principles or values which underlie it. The court should then use this view of the law in order to justify its decision in a new case which comes before it. On such an approach, then, once courts establish what the settled law is, they should then interpret law in applying it to a new case such that their decision is in accord with the most coherent account which justifies that settled law.

3.3 Coherence in Legal Reasoning: Necessary, Sufficient or Desirable?

Once a stance has been taken on the nature of the coherence relation in the case of law, many further questions concerning the role which considerations of coherence are to play in legal reasoning come to the fore. One important issue is that of how much emphasis is to be placed on coherence in justifying a judicial decision. Is exhibiting some degree of coherence with the existing law a necessary requirement of any justified judicial decision? Is it both a necessary and sufficient requirement, such that an account of the role of coherence in adjudication supplies us with a complete explanation of how judges should decide cases according to law? Or is coherence rather to be regarded as a desirable feature of judicial decision making, but one which can be overridden by other considerations in certain circumstances?

At this point in the discussion, it is possible to draw out some further possible links between the two concepts with which this entry is concerned, namely interpretation and coherence. If we hold that legal reasoning in sense (b), namely reasoning from the content of the law to the outcome which judges should adopt in a case before them, is wholly (Dworkin 1986) or mainly (Raz 1996a) interpretive, then we can reformulate some of the questions raised above concerning how much emphasis is to be placed upon coherence in adjudication in terms of the extent to which, in interpreting the law, we should interpret it in

such a way as to realise the value of coherence in judicial decisions. So, for example, is coherence the sole desideratum which should guide judges in interpreting the law, or is it merely one feature of a successful such interpretation, and, moreover, is it a necessary feature, or one which, although desirable, may be overridden by competing values which judges should also try to realise in interpreting the law?

Levenbook 1984 contends that it is a necessary condition for a judicial decision to be legally justified that it coheres with some part of the established law. She contrasts her understanding of this requirement with that adopted by MacCormick 1978. According to Levenbook, while MacCormick also holds that minimal coherence with some part of the established law is a necessary condition of a judicial decision being justified, he nevertheless contends that, so long as this minimal standard is met, further considerations of coherence which are also relevant to the decision can be defeated on consequentialist grounds. Levenbook's view is that this approach gives coherence too modest a role to play in legal reasoning; once a very minimal requirement of coherence is met, this value is too easily defeasible by other considerations. Levenbook finds this account of adjudication troubling because, in her view, it fails to do justice to judges' responsibility to be faithful to pre-existing law, a responsibility which places the judiciary in a quite different situation from the legislature when it comes to the question of how law ought to be developed. She contends that a judge who, within the limits allowed to him by the law, adopts a decision which is better on moral grounds over one which displays greater congruence with the trend or spirit of the existing law has made a mistake, and has adopted a legally unjustified decision. Levenbook very succinctly focuses the dilemma which judges must confront in deciding how much weight is to be placed on considerations of coherence in judicial decisions: should judges always adopt the outcome to a case which best coheres with the pre-existing law, or can they ever be justified in adopting an outcome which is less coherent but morally preferable? This way of focusing the dilemma which judges may face brings out another important aspect of coherence in legal reasoning, namely that granting a strong role to considerations of coherence is to place considerable emphasis on the backward-looking aspect of adjudication, as such an approach may require judges to place greater value on adhering to what has gone before, rather than on doing what would otherwise, on moral grounds, be the right thing.

Raz (1994a), who contends that coherence in legal reasoning is sometimes desirable, but certainly defeasible, poses essentially the same dilemma, but seems to place the burden of proof on those grasping the other horn of it. That is to say, Raz asks not how could it ever be justified for judges to deviate from the trend of the existing law in order to adopt a less coherent but otherwise morally preferable decision, but rather why should judges ever deviate from what is otherwise the morally best solution to a case before them on grounds of coherence? The burden of proof point is important because Raz's view seems to be that arguments in favour of a strong role for coherence in legal reasoning go through too easily, or are too readily adopted as a default position, perhaps because of the fact that reasoning by analogy is a common feature of many legal systems and seems to lend itself to being characterised in coherence terms, such that the facts speak for themselves in favour of the conclusion that considerations of coherence have a special role to play in legal reasoning. Pointing out that reasoning by analogy is not a necessary fact of life in all legal systems, and that, even where it does feature, it is still necessary to provide an explanation of the rationale of arguments from analogy, and the links between such arguments and coherence accounts of adjudication, Raz seeks to shift the burden of proof onto those who champion coherence. If judges are sometimes to deviate from what would otherwise be, according to law, the morally best

outcome to a case before them on grounds of coherence, then, Raz contends, we are in need of a convincing positive argument why this should be so.

3.4 Why Should Coherence Play a Role in Legal Reasoning?

One such argument may well be found in a point already mentioned in passing above, i.e. that judges are in a different position from legislators when it comes to deciding how the law ought to be developed. Raz (1979 and 1994a) argues that when faced with the choice of adopting the (according to law) morally best outcome to a case over an outcome which coheres better with the settled law, courts have to bear in mind that if they choose the former route, then some problematic consequences may ensue, such as that they may introduce conflicting rules reflecting conflicting social and economic purposes into the law, and hence create a considerable degree of dissonance with regard to existing legal doctrines in a given area of law. Such consequences need not dog legislative attempts to develop the law in a way which deviates from the doctrinal past, because legislative institutions have the power to sweep away the past in introducing new legislation, and to do so in such a way as to radically reform a whole area of law at one stroke. Courts, by contrast, can only make decisions concerning the issues arising in the case before them, and have considerably less opportunity to engage in radical reform of the law. These factors mean that judicial reform of the law will always be partial in nature, and, as was noted above, such partial reform brings with it the possibility of introducing dissonance and conflict into the law in the meantime. This may provide one reason why sometimes courts should give greater weight to considerations of coherence with pre-existing law in deciding cases which come before them, rather than striking out in a (albeit otherwise morally preferable) direction which coheres less well with settled law.

On Dworkin’s account of adjudication -- at least when that account is understood as a coherence account (see subsection 3.1 above) -- we find a different kind of answer to the question of why coherence has a special role to play in legal reasoning. As was noted in subsection 2.4, for Dworkin, in adjudicating cases, judges should seek to constructively interpret the law, i.e. to impose purpose on it in order to make of it the best possible example of the form or genre to which it is taken to belong (see Dworkin 1986, chs.2 & 3, and the entry on interpretivist theories of law). For Dworkin, the form or genre of law is to provide a convincing justification for the exercise of state coercion (see Dworkin 1986, *passim*; Dickson 2001, chs. 5 & 6), and, as he regards both judges and legal theorists as engaging in constructive interpretation (see Dworkin 1986, p90), Dworkin further contends that any adequate jurisprudential account of law must explain how what it takes to be law provides a general justification for the exercise of the coercive power of the state. In *Law’s Empire*, Dworkin argues that such a justification can best be provided when the law is viewed as the organised and coherent voice of what he refers to as a ‘community of principle’ i.e. a community whose members accept that their fates are linked by virtue of the fact that their rights and responsibilities are governed by common principles. So for Dworkin, we must interpret law as coherent, in the sense of speaking with one voice, because by so doing, we understand law as the voice of a community of principle, and so as capable of providing a general justification for the exercise of state coercion (see Dworkin 1986).

Some theorists are not so concerned to provide a ‘law-specific’ explanation of why coherence has an

important role to play in legal reasoning. For example, although acknowledging that there may be much more to be said about what is distinctive about legal reasoning, Hurley 1990 is largely content to explore the consequences for legal reasoning which ensue from the coherentist account of general practical reasoning which she espouses.

3.5 Coherence in Legal Reasoning: Global or Local?

In considering the role of coherence in legal reasoning, a final point to mention is that of how much of the law is to be made coherent according to various jurisprudential accounts granting a role to considerations of coherence. Are we talking of global coherence, such that judges should strive to reach judicial decisions which cohere to some extent with the settled law of an entire legal system, or should the coherence we seek be more local in nature, e.g. coherence with particular branches or areas of law?

Levenbook 1984 is a supporter of local coherence, and criticises those who, like Sartorius (1968 and 1971) and Dworkin (1977, and, although not yet written at the time of Levenbook's article, Dworkin 1986), hold that justified judicial decisions are those which best cohere with the law as a whole. According to Levenbook, champions of global coherence ignore the fact that sometimes a legally justified decision is supported by, in the sense of cohering with, principles which are distinctive of one area or branch of the law, but the principles concerned differ substantially from, and hence do not cohere well with principles from other branches of law. On this line of thinking, the judicial decision which coheres best with the principles underlying some specific field of law may not result in increased coherence of the entire system of law. That global coherence theorists may well be led to reject such a decision, and to hold that an alternative decision which coheres well with the overall system of law, but which increases incoherence locally is the more strongly justified, is, for Levenbook, a good reason to reject their theories: she contends that any plausible account of adjudication must make room for the kind of 'area-specific coherence' which she believes is necessary in the case of law. Raz 1994a also champions local over global coherence in adjudication, and his argument mentioned in the previous section concerning the limitations on the reforming role of courts, and the way in which this sometimes militates in favour of coherence playing a role in judicial decision making, is intended to support local coherence only. Peczenik 1994 claims that while the goal of the kind of doctrinal interpretation undertaken by legal scholars (which he refers to as 'legal dogmatics') is to establish the unity of an entire legal system, the judicial interpretation undertaken by judges is of a far more local variety, as it is concerned merely with the norms applicable to the case in question, and because a coherent interpretation of those norms may decrease their coherence with other legal norms.

While, as Levenbook 1984 notes, Dworkin's account of integrity in adjudication requires judges to attempt to view the legal system as a whole as exhibiting coherence and speaking with one voice in interpreting the law, Dworkin does also recognise that compartmentalisation into different branches or areas of law is an indisputable feature of legal practice, and he accordingly attempts to integrate it within his vision of adjudicative integrity. He does so via his doctrine of local priority in interpretation, i.e. that if a given principle justifying a judicial decision does not fit at all well with the area of law which the case is classified as falling under, then this counts dramatically against deciding the case in accordance with that principle, no matter how well such an interpretation coheres with other areas of the law (see Dworkin

1986, ch. 7). However, because of the strong pull toward global coherence in law as integrity -- expressed in Dworkin's claim that it is necessary to strive to view the legal system as a whole as speaking with one voice, the voice of an authentic political community, in order that law can be seen as justifying state coercion -- the current compartmentalisation of the law is not an unrevisable given for judges deciding cases, rather, it, too, is something which is subject to the Dworkinian process of constructive interpretation. This being so, he claims, when the compartmentalisation of the law does not track widely held principles of those subject to the law accounting current classificatory boundaries as important, then the doctrine of local priority is to be given much less force. Indeed, where there is a serious mismatch between the current compartmentalisation and actual views about relevant similarities and differences between areas of law held by those subject to it, it might be possible for judges to discard the doctrine of local priority altogether, and undertake radical reform of some departments of law in order to make them cohere better with others, or even to erase entire the alleged boundaries between certain branches of law in the course of interpreting the law and applying it to new cases.

Integrity

Integrity is one of the most important and oft-cited of virtue terms. It is also perhaps the most puzzling. For example, while it is sometimes used virtually synonymously with 'moral,' we also at times distinguish acting morally from acting with integrity. The person of integrity may in fact act immorally -- though they would usually not know they are acting immorally. Thus one may acknowledge a person to have integrity even though that person may hold importantly mistaken moral views.

When used as a virtue term, 'integrity' refers to a quality of a person's character, however, there are other uses of the term. One may speak of the integrity of a wilderness region or an ecosystem, a computerized database, a defense system, a work of art, and so on. When it is applied to objects, integrity refers to the wholeness, intactness or purity of a thing -- meanings that are sometimes carried over when it is applied to people. A wilderness region has integrity when it has not been corrupted by development or by the side-effects of development, when it remains intact as wilderness. A database maintains its integrity as long as it remains uncorrupted by error; a defense system as long as it is not breached. A musical work might be said to have integrity when its musical structure has a certain completeness that is not intruded upon by uncoordinated, unrelated musical ideas, that is, when it possesses a kind of musical wholeness, intactness and purity.

Integrity is also attributed to various parts or aspects of a person's life. We speak of attributes such as professional, intellectual and artistic integrity. However, the most philosophically important sense of the term 'integrity' relates to general character. Philosophers have been particularly concerned to understand what it is for a person to exhibit integrity throughout their life. Acting with integrity on some particularly important occasion will, philosophically speaking, always be explained in terms of broader features of a person's character and life. What is it to be a person *of* integrity? Ordinary discourse about integrity involves two fundamental intuitions: first, that integrity is primarily a formal relation one has to oneself, or between parts or aspects of one's self; and second, that integrity is connected in an important way to acting morally, in other words, there are some substantive or normative constraints on what it is to act with integrity. How these two intuitions can be incorporated into a consistent theory of integrity is not obvious, and most accounts of integrity tend to focus on one of these intuitions to the detriment of the other. A number of accounts have been advanced, the most important of them being: (i) integrity as the integration of self; (ii) integrity as maintenance of identity; (iii) integrity as standing for something; and (iv) integrity as moral purpose. These accounts are reviewed below. We then examine an issue that has been of central concern to philosophers exploring the concept of integrity: the relation between integrity and moral theory. Do moral theories such as utilitarianism allow room for people to live with integrity?

Integrity as Self-Integration

On the self-integration view of integrity, integrity is a matter of persons integrating various parts of their personality into a harmonious, intact whole. Understood in this way, the integrity of persons is analogous to the integrity of things: integrity is primarily a matter of keeping the self intact and uncorrupted. There are a variety of ways of developing this picture, depending on the concept of self and of integration that are employed.

One instructive attempt to describe the fully integrated self is Harry Frankfurt's. (Frankfurt 1987, pp. 33-34) Frankfurt does not explicitly address himself to the problem of defining integrity, nonetheless he does describe an important and influential account of self-integration. According to Frankfurt, desires and volitions (acts of will) are arranged in a hierarchy. First-order desires are desires for various goods; second-order desires are desires that one desire certain goods, or that one act on one first-order desire rather than another. Similarly, one may will a particular action (first-order volition) or one may will that one's first order volitions are of a particular sort (second-order volition). Second-order desires and volitions pave the way for third-order desires and volitions, and so on. According to Frankfurt, wholly integrated persons bring these various levels of volition and desire into harmony and fully identify with them at the highest level. There are various ideas as to what it means to fully identify with higher-level desires and volitions. However, such identification appears to involve knowing them; not deceiving oneself about them; and acting on them (usually).

A person is subject to many conflicting desires. If one simply acted at each moment out of the strongest current desire, with no deliberation or discrimination between more or less worthwhile desires, then one clearly acts without integrity. Frankfurt calls such a person a ‘wanton’ (Frankfurt 1971). Integrity thus requires that one discriminate between first-order desires. One may do this by endorsing certain first-order desires and ‘outlawing’ others. For instance, one may endorse a desire to study and ‘outlaw’ a desire to party, and do so by reference to a higher order desire ranking success over fun. Second-order desires may conflict. One may value success over fun, but also both fear that a ruthless pursuit of success will make one boring and value being fun over being boring. Fully integrated persons will not fall victim to such conflict; they will either avoid it altogether (if they can) or resolve the conflict in some way.

Resolution of self-conflict may be achieved by appeal to yet higher level desires or volitions, or by deciding to endorse one set of desires and outlawing others. At some point the full integration of one's self will require that one decide upon a certain structure of higher level desires and order one's lower level desires and volitions in light of it. As Frankfurt puts it, when a person unreservedly decides to endorse a particular desire:

> the person no longer holds himself at all apart from the desire to which he has committed himself. It is no longer unsettled or uncertain whether the object of that desire -- that is, what he wants -- is what he really wants: The decision determines what the person really wants by making the desires upon which he decides fully his own. To this extent the person, in making a decision by which he identifies with a desire, *constitutes himself*. (Frankfurt 1987, p. 38)

When agents thus constitute themselves without ambivalence (that is, unresolved desire for a thing and against it) or inconsistency (that is, unresolved desire for incompatible things), then the agent has what Frankfurt calls wholeheartedness. On one way of developing the integrated-self view of integrity, wholeheartedness is equated with integrity. It should be noted that self-conflict is not limited to desire. Conflict also ranges over commitments, principles, values, and wishes. Furthermore, all of these things -- desires, commitments, values, and so on -- are in flux. They change over time so that achieving the kind of ‘wholeheartedness’ that Frankfurt describes is a never-ending process and task. Self-knowledge is crucial to this process in so far as one must know what one's values, for example, are if one is to order them.

Frankfurt's account illustrates one way of describing the fully-integrated self. (See Taylor 1981 for a different approach.) The key question, however, is whether the idea of a fully-integrated self adequately captures the quality we ascribe when we say of someone that they are a person of integrity. There have been a number of criticisms of the integrated-self view of integrity. First, it places only formal limits on the kind of person who may be said to have integrity. People of integrity, however, are plausibly thought to be generally honest and genuine in their dealings with others. (See Halfon 1989, pp. 7-8.) Imagine a person who sells used-cars for a living and is wholeheartedly dedicated to selling cars for as much money as possible. Such a person will be prepared to blatantly lie in order to set up a deal. The person may well be perfectly integrated in Frankfurt's sense, but we should feel no temptation at all to describe them as having exemplary integrity.

Second, a person of integrity is plausibly said to make reasonable judgements about the relative importance of various desires and commitments. Yet, again, the self-integration view places only formal limits on the kind of desires that constitute a self. (See McFall 1987 pp. 9-11, Calhoun 1995 pp. 237-38). As McFall notes, one cannot say with a straight face something like: ‘Harold demonstrates great integrity in his single-minded pursuit of approval.’ (McFall 1987 p.9.) If integrity is nothing more than the perfect integration of self, however, it is hard to see how one can automatically deny Harold's integrity.

Third, on some accounts, the fully and perfectly integrated person is not able to experience genuine temptation. Temptation requires that the full force of an ‘outlaw’ desire be experienced, but successful

integration of the self may mean that such desires are fully subordinated to wholeheartedly endorsed desires and this may preclude an agent fully experiencing them. (See Taylor 1981 p.151 for an example of a view like this.) That a person experiences, and overcomes, temptation would count against their integrity on such a view. One might think, however, that a capacity to overcome temptation and display strength of character is in fact a sign of a person's integrity, not its lack. (Halfon 1989 pp. 44-7 urges this criticism.)

Fourth, Cheshire Calhoun argues that agents may find themselves in situations in which wholeheartedness tends to undermine their integrity rather than constitute it. (Calhoun 1995 pp.238-41. Analogously, Victoria Davion 1991 pp.180-192 argues that a person may change radically and yet maintain integrity.) In the midst of a complex and multifaceted life one may have compelling reasons to avoid neatly resolving incompatible desires. The cost of the resolution of all self-conflict may be a withdrawal from aspects of life that make genuine claims upon us. Resolving self-conflict at the expense of fully engaging with different parts of one's life does not seem to contribute to one's integrity. It seems rather like the sort of cop-out that undermines integrity. (One should not confuse integrity with *neatness*.)

The Identity View of Integrity

A related approach to integrity is to think of it primarily in terms of a person's holding steadfastly true to their commitments, rather than ordering and endorsing desires. ‘Commitment’ is used as a broad umbrella term covering many different kinds of intentions, promises, convictions and relationships of trust and expectation. One may be, and usually is, committed in many different ways to many different kinds of thing: people, institutions, traditions, causes, ideals, principles, projects, and so on. Commitments can be explicitly, self-consciously, publicly entered into or implicit, unself-conscious, private. Some are relatively superficial and unimportant, like casual support of a sporting team; others are very deep, like the commitment implicit in genuine love or friendship.

Because we find ourselves with so many commitments, of so many different kinds, and because commitments inevitably clash and change over time, it will not do to define integrity merely in terms of remaining steadfastly true to one's commitments. It matters which commitments we expect a person of integrity to remain true to. Philosophers have developed different accounts of integrity in response to this need to specify the kind of commitments that are centrally important to a person's integrity.

One option here is to define integrity in terms of the commitments that a person identifies with most deeply, as constituting what they consider their life is fundamentally about. Commitments of this kind are called ‘identity-conferring commitments’ or sometimes ‘ground projects’. This view of integrity, the identity view, is associated most closely with Bernard Williams. It is implicit in his discussion of integrity and utilitarianism (Williams 1973; we examine this discussion below) and also features in his criticism of Kantian moral theory (1981b). The idea is that for a person to abandon an identity-conferring commitment is for them to lose grip on what gives their life its identity, or individual character. An identity-conferring commitment, according to Williams, is ‘the condition of my existence, in the sense that unless I am propelled forward by the conatus of desire, project and interest, it is unclear why I should

go on at all.’ (Williams 1981b p.12).

One apparent consequence of defining integrity as maintenance of identity-conferring commitments is that integrity cannot really be a virtue. This is Williams's view. He argues that although it is an admirable quality, integrity is not related to motivation as virtues are. A virtue either motivates a person to act in desirable ways (as benevolence moves a person to act for another's good), or it enables a person to act in desirable ways (as courage enables a person to act well). If integrity is no more than maintenance of identity, however, it can play neither of these roles. On the identity view of integrity, to act with integrity is just to act in a way that accurately reflects your sense of who you are; to act from motives, interests and commitments that are most deeply your own. (Williams 1981a p.49) A further consequence of this view of integrity as maintenance of identity-conferring commitments is that there appears to be no normative constraints either on what such commitments may be, or on what the person of integrity can do in the pursuit of those commitments. The person of integrity can do horrific things and maintain their integrity so long as they are acting accordance with their core commitments.

A number of criticisms of the identity view of integrity have been made. First, integrity is usually regarded as something worth striving for and the identity account of integrity fails to make sense of this. (See Cox, La Caze, Levine 1999.) It disconnects integrity from the prevalent view that it is a virtue of some kind and generally praiseworthy. Second, the identity theory of integrity ties integrity to commitments with which an agent identifies, but acts of identification can be ill-informed, superficial and foolish. A person may, through ignorance or self-deception, fail to understand or properly acknowledge the source of their deepest commitments and convictions and we are unlikely to attribute integrity to a person who held true to a false and unrealistic picture of themselves. (On the other hand, this view of integrity as maintenance of identify-conferring commitments, recognizes the relevance of self-knowledge to *acting* with integrity. If a person fails to act on their core commitments, through self-deception, weakness of will, cowardice, or even ignorance, then they lack integrity.)

Third, on the identity view of integrity, a person's integrity is only at issue when their deepest, most characteristic, or core convictions and aspirations are brought into play. However, we expect persons of integrity to behave with integrity in many different contexts, not only those of central importance to them. (See Calhoun 1995, p.245.)

Fourth, as noted above, the identity view of integrity places only formal conditions upon the kind of person that might be said to possess integrity. The identity view of integrity shares this feature with the self-integration view of integrity and similar criticism can be made of it on this ground. It seems plausible to observe certain substantive limits on the kinds of commitments had by a person of integrity.

Integrity as Standing for Something

The self-integration and identity views of integrity see it as primarily a personal virtue: a quality defined by a person's care of the self. Cheshire Calhoun argues that integrity is primarily a social virtue, one that is defined by a person's relations to others (Calhoun 1995). The social character of integrity is, Calhoun

claims, a matter of a person's proper regard for their own best judgement. A person of integrity does not just act consistently with their endorsements, they stand for something: they stand up for their best judgement within a community of people trying to discover what in life is worth doing. As she puts it:

> Persons of integrity treat their own endorsements as ones that matter, or ought to matter, to fellow deliberators. Absent a special sort of story, lying about one's views, concealing them, recanting them under pressure, selling them out for rewards or to avoid penalties, and pandering to what one regards as the bad views of others, all indicate a failure to regard one's own judgment as one that should matter to others. (Calhoun 1995 p. 258)

On Calhoun's view, integrity is a matter of having proper regard for one's role in a community process of deliberation over what is valuable and what is worth doing. This, she claims, entails not only that one stand up, unhypocritically, for one's best judgement, but also that one have proper respect for the judgement of others.

Calhoun's account of integrity promises to explain why it is that the fanatic lacks integrity. It seems intuitively very plausible to distinguish between fanatical zeal and integrity, but the self-integration and identity views of integrity threaten to make the fanatic a paradigm case of a person of integrity. Fanatics integrate desires and volitions of various orders in an intimidatingly coherent package; they remain steadfastly true to their deepest commitments like no others. On Calhoun's view of integrity, however, we can locate a distinction between integrity and fanaticism. Fanatics lack one very important quality that, on Calhoun's view, is centrally important to integrity: they lack proper respect for the deliberations of others. What is not clear in Calhoun's account, and is in fact very hard to get clear on in any case, is what the *proper* respect for other's views in the end amounts to. Exemplary figures of integrity often stand by their judgement in the face of enormous pressure to recant. How, then, is one to understand the difference between standing up for one's views under great pressure and fanatically standing by them? Calhoun's claim that the fanatic lacks integrity because they fail to properly respect the social character of judgement and deliberation sounds right, but most of the work is done by the idea of ‘proper respect’ -- and it is not clear what this in the end comes to. Her view appears to allow for the possibility that integrity can accommodate the very kind of fanaticism (for example, the virtuous Nazi) that she wishes her account of integrity to eschew.

Calhoun's account of integrity places no conceptual constraints on the kinds of commitments that a person of integrity may endorse. It does not seem necessary on her view that a person of integrity have a special concern with acting morally. Although they have a special concern to understand what in life is worth doing, the person of integrity is not constrained to give moral, other-regarding answers to this question. The following account of integrity is explicitly concerned with attitudes towards morality.

Integrity as Moral Purpose

Another way of thinking about integrity places moral constraints upon the kinds of commitment to which a person of integrity must remain true. There are several ways of doing this. Elizabeth Ashford argues for

a virtue she calls ‘objective integrity’. Objective integrity requires that agents have a sure grasp of their real moral obligations. (Ashford 2000 p. 246.) A person of integrity cannot, therefore, be morally mistaken. Understood in this way, one only ascribes integrity to a person with whom one finds oneself completely in moral agreement. This concept of integrity does not, however, closely match ordinary use of the term. The point of attributing integrity to another is not to signal unambiguous moral agreement. It is often to ameliorate criticism of another's moral judgement. For example, we may disagree strongly with the Pope's views of the role of women in the Church, take this to be a significant moral criticism of him, and yet admit that he is a man of integrity. In such a case it is largely the point of attributing integrity to open a space for substantial moral disagreement without launching a wholesale attack upon another's moral character.

Mark Halfon offers a different way of defining integrity in terms of moral purpose. Halfon describes integrity in terms of a person's dedication to the pursuit of a moral life and their intellectual responsibility in seeking to understand the demands of such a life. He writes that persons of integrity:

> embrace a moral point of view that urges them to be conceptually clear, logically consistent, apprised of relevant empirical evidence, and careful about acknowledging as well as weighing relevant moral considerations. Persons of integrity impose these restrictions on themselves since they are concerned, not simply with taking any moral position, but with pursuing a commitment to do what is best. (Halfon 1989, p. 37.)

Halfon's view allows that integrity is not necessarily ‘objective’, as Ashford claims, and is similar in a number of respects to Calhoun's. Both see integrity as centrally concerned with deliberation about how to live. However, Halfon conceives this task in more narrowly moral terms and ties integrity to personal intellectual virtues exercised in pursuit of a morally good life. Halfon speaks of a person confronting ‘all relevant moral considerations’, but this turns out to be quite a formal constraint. What counts as a relevant moral consideration, on Halfon's view, depends upon the moral point of view of the agent. Persons of integrity may thus be responsible for acts others would regard as grossly immoral. What is important is that they act with moral purpose and display intellectual integrity in moral deliberation. This leads Halfon to admit that, on his conception of integrity, it is possible for a Nazi bent on genocide of the entire Jewish people to be a person of moral integrity. Halfon thinks it possible, but not at all likely. (Halfon 1989 pp. 134-36)

Other philosophers object to this consequence. If the genocidal Nazi is a possible object of ascriptions of moral integrity, then we can properly ascribe integrity to people whose moral viewpoint is bizarrely remote from any we find intelligible or defensible. (See McFall 1987. Putnam 1996 draws on the work of Carol Gilligan 1982 to suggest a different way of overcoming the problem of the Nazi of integrity.) Moral constraints upon attributions of integrity need not take the form of Ashford's ‘moralized’ view or Halfon's more limited formal view. One might say instead that attributions of integrity involve the judgement that an agent acts from a moral point of view those attributing integrity find intelligible and defensible (though not necessarily right) -- and that this formal constraint does have substantive implications. It prohibits attributing integrity to, for example, those who advocate genocide, or deny the moral standing of people on, for example, sex-based or racial grounds. There are things which a person of

integrity cannot do. The Nazis and other perpetrators of great evil were either committed to what they were doing, in which case they were immoral (or not moral agents at all) and lacked integrity; or else they lacked integrity because they were self-deceived or dissembling and never had the Nazi commitments they alleged to have, and acted upon, at all. Judgements of integrity would thus involve judgement about the reasonableness of other's moral points of view, rather than the absolute correctness of their view (Ashford) or the intellectual responsibility with which they generally approach the task of thinking about moral questions (Halfon).

Defining integrity in terms of moral purpose has the advantage of capturing intuitions of the moral seriousness of questions of integrity. However, the approach appears too narrow. Halfon's identification of integrity and moral integrity appears to leave out important personal aspects of integrity, aspects better captured by the other views of integrity we have examined. Integrity does not seem to be exclusively a matter of how people approach plainly moral concerns. Other matters like love, friendship and personal projects seem to be centrally important. Imagine a person who sets great store in writing a novel, but who postpones the writing of it for years on one excuse or another and then abandons the idea of novel-writing after one difficult experience with a first chapter. We would think this person's integrity diminished by their failure to make a serious attempt to see the project through, yet the writing of a novel need not be a moral project. (See McFall 1987 on the difficulty of bringing together personal and moral aspects of integrity.)

All of the accounts of integrity we have examined have a certain intuitive appeal and capture some important feature of our concept of integrity. There is, however, no philosophical consensus on the best account. It may be that the concept of integrity does not lend itself to a single coherent description. Integrity may be a cluster concept, tying together different, overlapping qualities of character under the one term. On the other hand, it may be that a fully adequate account of integrity is simply yet to emerge.

Integrity and Moral Theory

Despite the fact that it is somewhat troublesome, the concept of integrity has played an important role in contemporary discussion of moral theory. An important and influential line of argument, first developed by Bernard Williams, seeks to show that certain moral theories do not sufficiently respect the integrity of moral agents. (See Williams 1973 & 1981.) This has become an important avenue of critique of modern moral theory. (See, for example, Scheffler 1993 and Lomasky 1987.)

Modern moral theories, the most representative of which are utilitarianism and Kantian moral theory, do not concern themselves directly with virtue and character. Instead, they are primarily concerned to describe morally correct action. Theories of morally correct action generally aspire to develop criteria by which to categorize actions as morally obligatory, morally permissible, or morally impermissible. Some theories of morally correct action also introduce the category of the supererogatory: an action is supererogatory if and only if it is morally praiseworthy, but not obligatory. The two theories of primary concern to Williams are utilitarianism and Kantian moral theory, and both of these are usually interpreted as eschewing the category of the supererogatory. (See Baron 1995 for an argument that Kantian moral

theory has no need for the category of the supererogatory.) Williams maintains that both utilitarianism and Kantian moral theory are deeply implausible because of their integrity undermining effects. His argument against utilitarianism makes the more transparent appeal to the concept of integrity and it is this argument that we examine here. (But see Herman 1983, Rogerson 1983, Jensen 1989, and Baron 1995, chapter four, for critical discussion of the Williams's argument against Kantian moral theory.)

Williams's argument against utilitarianism is directed against a particular version of utilitarianism -- act-utilitarianism. This is, very roughly, the view that an agent is to regard as morally obligatory all and only actions that maximize general well-being. The act-utilitarian theory that Williams criticizes has an important feature: it aspires to describe the correct form of moral *deliberation*. It does more than specify what it is for an action to be morally correct, it specifies how an agent should think about moral decisions. Agents should think about which of the actions available to them will maximize general well-being and decide to act accordingly. Notice that this theory is completely impartial and that it makes no room for an agent to give special weight to personal commitments, causes, projects, and the like. Act-utilitarianism recognizes no personal sphere of activity in which moral reflection operates merely as a side-constraint.

According to Williams, an agent who adopted this version of utilitarianism would find themselves unable to live with integrity. As he puts it, to become genuinely committed to act-utilitarianism is for a person to become alienated:

> in a real sense from his actions and the source of his actions in his own convictions. It is to make him into a channel between the input of everyone's projects, including his own, and an output of optimific decision; but this is to neglect the extent to which *his* actions and *his* decisions have to be seen as the actions and decisions which flow from the projects and attitudes with which he is most closely identified. It is thus, in the most literal sense, an attack on his integrity. [Williams (1973, p.117)]

Williams's argument is based on the identity theory of integrity, discussed above. Integrity, on this view, requires that persons act out of their own convictions, that is, out of commitments with which they deeply identify. Act-utilitarianism seeks to replace personal motivations of this kind with impartial utilitarian reasoning. Williams's argument appears to make acting with integrity incompatible with acting in accordance with act-utilitarianism.

Williams develops the point with two famous and much discussed examples. (1972, pp.97-99). The example which best illustrates his argument involves the figure of George, a recent doctoral graduate in chemistry who is having difficulty finding work. George has young children. He also has poor health, limiting his job opportunities. George's (unnamed) wife must work to support the family and on Williams's story this causes a great deal of strain on the family. George has a strong commitment to pacifism, a conviction amounting to an identity-conferring commitment. A dilemma arises for George when more senior colleague tells him about a decently paid job in a laboratory doing work on biological and chemical warfare. If George does not take up the job, it will almost certainly go to another chemist, one without George's pacifist commitment, who will pursue the development of biological and chemical

weapons more vigorously than George. Should George take the job or not?

The most likely act-utilitarian conclusion here is that George should accept the job. This would contribute greatly to the well-being of his family as well as probably contributing to general welfare by forestalling some relatively zealous development of weapons of mass destruction. Weighed in the balance are George's feelings in the matter. The utilitarian calculation, if it really does come out this way, is demanding a sacrifice of George: that he put aside his opposition to, and distaste for, biological and chemical weapons development and deal with the anguish and alienation that may result from working in the laboratory.

According to Williams, however, act-utilitarianism in fact demands a different kind of sacrifice from George. It demands that he act without integrity, abandoning or ignoring a longstanding, identity-conferring commitment to pacifism simply because maximum general well-being is to be found elsewhere. This is just one, particularly acute, example of the tendency of impartial utilitarian deliberation to run roughshod over identity-conferring commitments, treating them as no more than one source of utility among others. In general, Williams concludes, identity-conferring commitments cannot play the kind of role in act-utilitarian moral deliberation that is required for an agent to act with integrity, that is, for an agent to act with genuine conviction in matters of grave, identity-determining importance to them.

Williams's critique of utilitarianism has spawned a large and important literature in which the argument has been interpreted and reinterpreted, redrafted, and much criticized. There are, nonetheless, three main lines of response to the Williams's critique of utilitarianism. We consider them in turn. The first reply essentially concedes the point and offers in response a development of utilitarian moral theory, one aimed at avoiding the flaws that Williams sought to demonstrate. One way to do this is by watering down the impartiality of utilitarian theory, explicitly factoring in the permissibility of giving extra weight to one's own personal projects, commitments, and so on. (See Scheffler 1993 for a development of this view, and Harris 1989a and 1989b for criticism of the adequacy of this response.)

Another way to try and improve utilitarianism in response to Williams's argument is to advance a less ambitious form of utilitarian moral theory. Recall that Williams criticizes a version of act-utilitarian *moral deliberation*, so one may respond to it by describing a version of act-utilitarianism that does not dictate the form of moral deliberation. A moral theory, on this view, primarily describes morally correct action and does not automatically entail a theory of correct moral deliberation. Thus one might subscribe to an act-utilitarian account of morally correct action whilst not demanding that someone like George approach life by deliberating in strictly utilitarian ways. There are however, a number of difficulties with separating out theories of morally correct action and correct moral deliberation in this way. For one thing, it appears to deprive a theory of morally correct action of much point. What is the point, one might ask, of subscribing to a moral theory if it offers no clear practical guidance on how one should act? (See Williams 1981a for a discussion of this point.) Nonetheless, there have been attempts to develop and to motivate versions of utilitarianism not prescribing methods of moral deliberation. (See Railton 1986 for development of such a view and Harcourt 1998 for criticism of it.)

A second possible line of response to the argument is to deny the presupposition of Williams's argument that it is absurd for a moral theory to undermine integrity. It may just be that moral demands upon us really are very stringent, and identity-conferring commitments must sometimes (perhaps often) be sacrificed in the interests of, say, our acting to ameliorate preventable suffering. One might even consider it a virtue of utilitarianism that it demonstrates how genuinely difficult it is to preserve one's integrity when confronting a world of massive and easily preventable suffering. (See Ashford 2000 for an argument along these lines.)

The third, and most influential, line of response argues directly against the idea that utilitarianism demands that agents act against their convictions. Utilitarianism demands that agents adopt utilitarian ideals; that agents give utilitarian ideals the kind of priority that would have them function as the central identity-conferring commitments of their life. Thus utilitarianism does not demand that one live without identity-conferring commitments at all, but that one live with *utilitarian* identity-conferring commitments. Were George a utilitarian, he would not have been acting against his convictions by taking a job in the chemical weapons factory. He does not lose his integrity simply in virtue of his commitment to utilitarianism. Williams appears to confuse the case in which a utilitarian George acts against his personal interests (in which case his integrity would be preserved) with the case in which a non-utilitarian George is somehow persuaded to act as a utilitarian (in which case his integrity would not be preserved). Acting as a utilitarian when one has no sympathy with utilitarianism may well diminish one's integrity, but such a loss of integrity is not attributable to utilitarianism and has no bearing on utilitarianism's plausibility as a moral theory. (See Carr 1976, Trianosky 1986 and Blustein 1991 for versions of this criticism.)

The matter is not finally settled, however, for notice that Williams's critique is premised on a version of the identity theory of integrity. As we have seen, there are other plausible candidates for an account of integrity and the critique of utilitarianism may well succeed better in their terms. The key issues are whether utilitarian commitment is compatible with a fully satisfactory account of integrity, and if so, whether integrity is of such value and importance that the clash between integrity and utilitarian commitment undermines the plausibility of utilitarian moral theory. An adequate account of integrity needs to deal with these issues and to capture basic intuitions about the nature of integrity: that persons of integrity may differ about what is right but a moral monster cannot have integrity.

Francis of Marchia

Francis of Marchia was perhaps the most exciting theologian active at the University of Paris in the quarter century between the Franciscan Peter Auriol (fl. 1318) and the Augustinian Hermit Gregory of Rimini (fl. 1343). Although he had innovative and even influential ideas in philosophical theology, natural philosophy, and political philosophy, until recently he has been little studied.

Life and Work

Francis of Marchia (a.k.a. de Appignano, de Pignano, de Esculo, de Ascoli, Franciscus Rubeus, and the *Doctor Succinctus*) was born ca. 1290 in the village of Appignano del Tronto in the province of Ascoli Piceno, east of Rome and near the Adriatic. He became a Franciscan and rose in the order's educational hierarchy until he lectured on the *Sentences* at the Franciscans' Paris *studium* in 1319–20. From his Paris years (1319–23 or 24) we have a popular commentary on the four books of the *Sentences*, extant in at least ten manuscripts for each book, and in at least two distinct redactions for the first two books. From the same period stems Marchia's short commentary on the first two books of the *Metaphysics*. By 1324, when he was lector at the Franciscans' *studium* in Avignon, Marchia had become Master of Theology. Perhaps his *Quodlibet* derives from theological debates held in Avignon. Marchia's literal commentary on the *Physics* and his more independent long commentary or questions on the first seven books of the *Metaphysics* probably belong to his Paris or Avignon period. In 1328, Marchia fell out with Pope John XXII for supporting the Franciscan Minister General Michael of Cesena on the issue of apostolic poverty, left Avignon, and eventually took refuge with the Holy Roman Emperor Louis of Bavaria along with William of Ockham, Marsilius of Padua, and others. During this period Marchia wrote his

Improbatio against John XXII. Marchia was eventually captured, and he confessed and retracted his errors before the Inquisition in 1341, or perhaps 1336 (a possibility suggested in Wittneben-Lambertini 1999). He was reconciled with the Church, and died some time after 1344.

Until 1991 almost none of Marchia's writings were published and only Anneliese Maier devoted serious and sustained attention to his thought. Since then, however, Nazareno Mariani has published three volumes of Marchia's works (Marchia 1993, 1998, and 1997b): the *Improbatio*, the *Physics* commentary, and the *Quodlibet*, the last of which includes roughly a quarter of the main version — the *Scriptum* — of book I of the *Sentences* commentary, and two questions from book II, in appendices. In a 1991 monograph on Marchia's cosmological thought (Schneider 1991, 29), Notker Schneider announced the edition of the *Metaphysics* commentary, building on the work of Albert Zimmermann (Marchia 1965, Zimmermann 1966). Schneider, Russell Friedman, and Christopher Schabel have added to Mariani's efforts in editing sections of the *Sentences* commentary (Marchia 1991b, 1997a, 1999a, 1999b, 2000, 2001). Currently, Mariani is editing the *Reportatio* for book I, while Friedman and Schabel are occupied with the *Scriptum* on the same book. The Centro Studi Francesco d'Appignano was established in Marchia's hometown in May of 2001 during the First International Conference on Francis of Marchia. The second such conference is planned for 2003. Finally, the journal *Picenum Seraphicum*, edited by Roberto Lambertini, promises to be a forum for Marchia studies.

Philosophical Theology

Marchia's main and most popular writing, larger than all his other works combined, is the *Sentences* commentary. Although this genre of scholastic writing contains much material that we would call pure science, especially in Marchia's case (see Natural Philosophy below), it is primarily a vehicle for philosophical theology. Here it must be stressed at the outset that Francis of Marchia was **not** a faithful Scotist, contrary to a common opinion based on misconceptions from early in the twentieth century. Most recent research has proven that Marchia generally rejected or severely modified John Duns Scotus's doctrines, rather than followed them, even in the specific contexts like Trinitarian theology where he was claimed to have been a loyal Scotist (Marchia 1999a). For example, Marchia was uncomfortable with Scotus's stress on and use of a strong distinction between the divine intellect and will, and this led Marchia to oppose Scotus on issues such as the procession of the Holy Spirit and the mechanism of divine foreknowledge. Indeed, it seems that Marchia was perhaps less of a Scotist than any of the other continental Franciscans active between Peter Auriol and the Black Death. Nevertheless, Scotus forms much of the backdrop for Marchia's theology. The other thinker against whose theories Marchia often developed his own doctrine was Auriol, whose *Sentences* commentary Marchia appears to have known in a *Reportatio* version.

A critical edition of one redaction of Marchia's *Sentences* commentary would probably take up about five large volumes. It is roughly equal in size to that of his contemporary and confrère Landulph Caracciolo. Whereas Caracciolo's commentary is frequently a disjointed, point-by-point refutation of Peter Auriol and defense of Scotus on many issues, however, Marchia was more selective in choosing his topics, more independent in giving his determination, and generally more eloquent. For example, Marchia asks only

one brief question on the Immaculate Conception, a favorite Franciscan topic (book III, q. 8, and because of a missing quire this question is not present in the most studied manuscript, Vat. Chigi. lat. B VII 113), showing himself to support the immaculatist position, but he asks a great number of questions in books I, II, and IV on the relationship between the will and intellect.

Thus, although Auriol's controversial opinions on epistemology and divine foreknowledge drew fire from Caracciolo and most other Paris theologians up to Gregory of Rimini's day, even from Oxford Franciscans, Marchia devoted much energy to foreknowledge but almost ignored the great debate over intuitive and abstractive cognition. Aside from an isolated mention of "intuitive cognition" in *Scriptum* I, d. 3, q. 4, and of "intuitive vision" in the very last question in book IV, Marchia merely discusses the problem in passing on two brief occasions: first, in book II, q. 25 (Marchia 1997b, p. 322), while treating angelic knowledge, and second, in book III, q. 13, in the context of the beatific vision of the Word (not yet edited). In the latter case, the more substantial passage, he gives a somewhat Scotistic definition: "Intuitive and abstractive cognition are not distinguished according to having a species or not, but only according to the disposition of the object, because if the object is present, the species represents it intuitively; if absent, it represents it abstractively." Therefore, "the same species that is intuitive in the presence of the object is abstractive in the absence of the object." Marchia adds in agreement with Auriol that God "can cause the act of seeing without the object," and that a species of a created object "indifferently represents" a present or absent object. Although this might provoke some epistemological questions, Marchia turns to the vision of the Essence and leaves human cognition *in via* aside.

In contrast, Marchia singled out divine foreknowledge for special treatment, devoting three entire distinctions (*Scriptum* I, dd. 35, 36, and 38) to the issue and concentrating most of his discussion on the reconcilation of foreknowledge with human free will (Marchia 1999b, 2000; Schabel 2000). Here Marchia was opposed in some way to just about everyone else who had written on the issue, but mainly Auriol, who had claimed that any determination prior to the coming about of a contingent event destroyed contingency, including the truth or falsity of future-contingent propositions. Marchia's defense of the application of the Principle of Bivalence to propositions about the contingent future was the model for Gregory of Rimini. But having shown that such propositions are either determinately true or false, Marchia went on to articulate a type of prior determination that saved foreknowledge while preserving contingency. In fact, according to Marchia, there *must* be some determination in the causes of future contingent events prior to their actual occurrence, otherwise nothing would occur:

> And I ask about that determination in the cause, was it in the cause before the placing of the effect [into reality] or not? If it was, then I have my point. If not, I ask, how is the effect determined in its cause before it is put into being, necessarily or contingently? If necessarily, then it comes about necessarily, according to this opinion. If contingently and a contingent is not determined to one side in its cause, then that determination is not determined except through some prior contingent determination. And I would ask of this just as before, will it go on infinitely, or is it necessary to stop at some contingent determination in the cause before the effect? (d. 35: Marchia 1999, p. 75)

Marchia, however, was aware that Auriol had claimed that any such prior determination was fatal for

contingency, so Marchia draws a distinction between different indeterminations and determinations, perhaps expanding on isolated remarks made by Scotus. There is (1) an indetermination ‘about the possible’ (*de possibili*), with respect to being able to act and being able not to act. With this indetermination, we are *not* determined *de possibili* before an event, so we are free and act contingently and not necessarily. There is also (2) a posterior indetermination ‘about inhering’ (*de inesse*), with respect to what will be the case in reality. This indetermination toward what will inhere in reality, however, would be an *obstacle* to foreknowledge and, for us, to acting. Thus it must be replaced by (3) a determination in the contingent cause toward acting, both for the future to be known and for us to act. The (4) determination *de possibili*, toward being able to act or being able not to act, is absent from free causes until the event occurs, at which time our freedom and power with respect to that event are removed.

An obvious objection is that, for Marchia, the effect is determinate in the cause before the action of the cause, and thus that determination is ‘presupposed’ in the subsequent action of the cause. Since it is ‘presupposed’, that determination is not in the cause's power, and thus is not contingent. Marchia replies with another distinction:

> ‘Action’ can be taken in three ways: either it can be taken actually, namely when an agent is actually acting; or it can be taken virtually, when an agent can act although he is not acting; or it can be taken in a middle way, not purely actually nor purely virtually, but in a middle way as ‘dispositionally’ or ‘aptitudinally’, namely when an agent is not acting but is determined toward acting, although in actuality he is not acting — and he not only can act, but is determined to be acting later. Similarly there is a threefold ‘determination’ of the agent: one actual, by which an agent actually determinately puts one part of a contradiction into effect; a second is a potential determination by which an agent posits or can determine any part of a contradiction dividedly; the other is, as it were, a ‘dispositional’ or ‘aptitudinal’ determination, by which an agent is determined with respect to the future to putting one part of a contradiction [into effect]. Each determination presupposes the action corresponding to it, because an actual determination follows the action in actuality; the dispositional determination follows the action dispositionally, although it precedes the actual action; the potential determination follows the potential action, although it precedes that actual and dispositional action. (d. 35: Marchia 1999, pp. 89–90)

Thus when an agent is determined *de inesse* to doing something in the future, that determination is like a disposition, and neither actual, because the event has not yet occurred, nor potential, because the possibility to do otherwise is not removed. Such a determination is not ‘actually’ in the agent's power, Marchia grants, but it is in his power ‘dispositionally’, for although the agent cannot act before he acts, he can be disposed to act so that he will in fact act.

The foregoing example is representative of Marchia's thought in many ways. He frequently draws clever and original distinctions, and the *de possibili/ de inesse* division is employed in other contexts such as predestination (book I, d. 40: Marchia 2001). He makes similar innovative distinctions when discussing the different types of human and divine willing (*Reportatio* I, dd. 45-48: see attached edition). Although

one could argue about the cogency of Marchia's arguments, in the case of the *de possibili/ de inesse* distinction Marchia found a favorable response among the following, who adopted the device: his Franciscan successors at Paris in the next decade Aufredo Gonteri Brito, William Rubio, and William of Brienne; the Augustinian Hermits Michael of Massa and Gregory of Rimini; and, in the later fifteenth century, Fernando of Cordoba and Francesco della Rovere, who was to become Pope Sixtus IV. Thus in philosophical theology one could and often did look to Marchia for an alternative to Scotus and an innovative response to Auriol.

Natural Philosophy

Since the time of Pierre Duhem in the early twentieth century, Francis of Marchia has been known as a scientist, and looking through the titles of his questions, one finds an abundance of scientific topics related to such things as the infinite and the psychology of willing (Friedman-Schabel, 2001). In general, Marchia displays a great interest in the causal process. One thing that helps explain his popularity among historians of medieval science, and perhaps his own interest in scientific matters, is his clear and sharp distinction between natural causation that works necessarily and the contingent causation of human, angelic, and divine free will. In an influential passage containing echoes of Siger of Brabant, a passage to which Anneliese Maier first drew attention (*Scriptum* I, d. 36: Maier 1949; Marchia 2000), Marchia explains that there are two types of contingency in the world: first, there is contingency *per se, simpliciter*, *positiva*, and *intrinseca*. This is the contingency by which something is still able to occur or not occur even when all the required accidental, natural causes have been posited. There is only one source of such contingency: free will. Second, there is contingency *per accidens, secundum quid*, *privativa*, and *extrinseca*. This is the contingency of natural causation. A natural effect takes place as the result of many accidental causes. Some of these causes may be impeded by other natural, accidental causes, and so with respect to a small, limited number of causes a natural effect may be considered ‘contingent’. This does not mean that the natural effect is really and truly contingent without qualification in the first way, however, because if we take *all* of the natural effect's causes into account, the effect will *necessarily* follow, or not follow, as the case may be. That is, assuming God's contingent creation in the first place, and His ‘general influence’ that keeps the chain of causation in existence, natural causation works necessarily, and so with all of an effect's causes taken together, what happens in nature is necessary. Of crucial important for science is Marchia's further assertion that these ‘contingent’ effects can even be known by a *created* intellect. This is because the number of natural causes is not infinite. Thus a finite, created intellect can know the natural future with certainty. The only problem, says Marchia, is that we humans have a short life and an intellect that is bound with the body.

One of the most important innovations of the mature Galileo was the assertion that the celestial and terrestial realms are made of the same fundamental matter and therefore follow the same basic natural laws. Francis of Marchia put forth a similar hypothesis in his commentary on book II, qq. 29-32 (Marchia 1991b). Contrary to contemporary Aristotelian theory, Marchia argues that the heavens are not made up of a fifth, incorruptible, nobler element, which radically differentiates the supralunar realm from the sublunar one. On the contrary, the basic matter is the same everywhere, and just as Marchia considers the natural world to follow predictable patterns, he also thinks that those patterns are universally applicable.

These two tenets have important implications for the practice of natural philosophy (Schneider 1991).

With this attitude it is no wonder Marchia's physical theories drew the attention of medieval and modern scholars alike. The first important study on Marchia's thought was Anneliese Maier's partial edition and analysis of book IV, q. 1, of Marchia's *Sentences* commentary (Marchia 1940). There Marchia puts forth his famous forerunner to John Buridan's impetus theory of projectile motion. Aristotle had not provided a satisfactory explanation for why, when we throw a ball, for example, the ball keeps going even after we have released it. Marchia's explanation, which had its own partial predecessors, was that we leave behind a force in the ball — a *virtus derelicta* — that keeps the ball in motion. The fact that this force was temporary rather than permanent meant that it was not akin to the inertia theory of classical mechanics, but, as Marchia stated explicitly, it was a simple theory and did explain the phenomena in temporary projectile motion. Marchia also applied the theory to celestial motion, but he does not appear to have reconciled the semi-permanent nature of the motion of the heavens with the more ephemeral *virtus derelicta*. Maier saw reactions to Marchia's treatment in the works of Francis of Meyronnes, his follower Himbert of Garda, Nicholas Bonet, John Canonicus, William of Ockham, and Buridan, although it is hard to say whether he had much positive influence in this context.

Perhaps medieval scholars did not arrive at inertia because of their reluctance to consider motion in a vacuum. In observable projectile motion, at least in the fourteenth century, the projectile always ended up back on the ground. One of Aristotle's arguments for the impossibility of a vacuum was the lack of resistance of the medium. If velocity was a function of the proportion of force to the resistance of the medium, then with no resistance there would be motion in an instant, something usually considered an impossibility. In book II, q. 16, a. 5 of his *Sentences* commentary, however, Marchia has to wonder why an angel, which is not a "*corpus quantum*," or bodily mass, cannot move instantaneously, i.e. from one place to another without any temporal duration. Part of the answer is simply that it is a contradiction to be two places at once, but Marchia adds that there must be some sort of internal resistance in angels that makes instantaneous motion impossible. The notion of internal resistance unrelated to natural place (even though no *corpus quantum* is involved) and the concept of impetus (Buridan's making the *virtus derelicta* permanent) appear to be primitive versions of the ingredients of a theory of inertial mass. Since Marchia's writings predate those of his more famous successors, the Oxford Calculators and Buridan and Nicole Oresme at Paris, and some of his ideas at least resemble Galileo's in some way, Marchia's possible impact on later scientists is a good topic for future research.

Political and Social Thought

We are only just beginning to appreciate Marchia's thought in philosophical theology and natural philosophy. A fuller understanding requires, first of all, the critical edition of the *Sentences* commentary. We are in a better position to investigate where Marchia stands in political theory because of Mariani's publication of the *Improbatio* (Marchia 1993), probably written in the beginning of 1330. As in the case of Ockham, circumstances drove Marchia into opposition to Pope John XXII, and as a result Marchia's later writings focus on more worldly affairs. The group of scholars supporting the ex-minister general of the Franciscans Michael of Cesena gathered at Louis of Bavaria's court in Munich and collaborated on

their anti-John XXII tracts. It has been shown that Marchia's *Improbatio* influenced Ockham's *Opus nonaginta dierum* (Miethke 1969; Lambertini 2000) and most probably the Cesena group's *Appellatio magna monacensis* (Lambertini, forthcoming). Thus, as in philosophical theology and natural philosophy, Marchia had an historical impact.

The Franciscans maintained that they lived the most perfect life that was humanly possible, following the model of Christ and the apostles who, they claimed, possessed nothing either as individuals or in common. John XXII not only denied that Christ and the apostles had no possessions, but he also declared the Franciscan position to be heretical. The resulting quarrel came to touch on such issues as usury, ownership of property, disposal of property, natural and divine law and rights, papal infallibility, and ultimately the basis of sovereignty.

On the question on dominion, or possession, of property, Marchia accepted the pope's assertion that, even in the state of nature before the fall, Adam had dominion over the things he used, but Marchia denied that this type of dominion had much at all in common with post-lapsarian dominion: they are *alterius generis*, differing like violent and natural, like corruptible and incorruptible (Lambertini 2000, VII). Before the fall, Adam had "dominion of natural liberty and perfection," according to the "primaeval natural law"; afterwards, although Marchia admitted that there was a "remnant of natural law," basically it had to be replaced by positive law and the dominion of "servile necessity" and the "power of compulsion." This is because, if left to his own devices, post-lapsarian man would grab all he could get.

Marchia describes the situation in the state of nature thus:

> In the state of nature all things had been common to all people, not only with respect to the dominion of things but also with respect to use, whether *de iure* or *de facto* — with respect to use de iure because the right of using whatever was suitable to them had been common to all and proper to none. (Marchia 1993, pp. 154-5)

Moreover, even before the creation of Eve, Adam had no dominion over things that was "proper" to him. Therefore Pope John erred in claiming that the eventual "division of things" into private possessions stemmed from divine law, since it came from human or positive law, necessitated by human iniquity. The first division, by human law, occurred already with Cain and Abel before the Flood. Of course God restored common dominion to Noah and his sons with the Deluge, but humans and human law soon reinstated the division of goods. This was not by divine will, for "when they began to build the tower [of Babel] it was by human counsel, not by divine — indeed God was not pleased." By extension, the laws of emperors and princes derive from human law, not divine, with the exception of Hebrew law in the time before Christ, a special status lost at the crucifixion.

The upshot is that private property is not divinely instituted, for Marchia: it is a human introduction. In the state of nature, by divine law, humans had a common "dominion" over goods, but this dominion is not at all the dominion of human law, of private property. Moreover, it is this common dominion that Christ and the apostles followed. It is therefore humanly possible to do so, indeed the best possible way

to live, and the Franciscans approached it more closely than anyone else.

On the question of ecclesiastical power, of course, Marchia was also in disagreement with Pope John XXII (Lambertini 2000, IX). In order to defend Christ's poverty and that of the Franciscans by extension, Marchia interpreted Christ's remark to Pilate that "my kingdom is not of this world" as meaning not only that the origins of his kingdom and the source of his power are not of this world, but also that his kingdom and his power are not with respect to the things of this world. Indeed, for Marchia, Caesar had legitimate sovereignty over this world. Marchia thus denied that Christ, as a man, possessed any temporal power, and hence he rejected John XXII's claim that Christ was *rex* and *dominus* in a temporal sense. The implication is that the pope could not inherit temporal power over the entire earth, although Marchia admitted that the temporal sword could pertain to the pope indirectly and mediately.

Given that the few studies that have been done demonstrate that Marchia had an impact on his successors in many areas of philosophical thought, and given that it is only in the past decade that any substantial part of his works has been available in print, we can in the near future expect a flood of investigations of the ideas of this interesting and important scholastic thinker.

Critical Editions of Texts

The following texts are critical editions, using all known manuscript witnesses, which will be published in the future with apparatus criticus and fontium. Distinctions 35-48 of book I of the *Sentences* concern the unified themes of divine knowledge, power, and will. Marchia's *Scriptum* for book I ends prematurely at distinction 40, and distinction 39 on divine ideas is much trunctated. Since distinctions 35-40 of the Scriptum have been or are being published (Marchia 1999b, 2000, 2001), the following texts from the *Reportatio* for book I, distinctions 39, 42-44, and 45-48, will complement the *Scriptum* material on these subjects.

- Francis of Marchia, *Reportatio in primum librum Sententiarum*, Distinctio 39, 42-44, 45-48
- Francis of Marchia, *In secundum librum Sententiarum*, Quaestio 16, Articulus 5

In secundum librum Sententiarum by Francis of Marchia

Quaestio 16, Articulus 5

Quantum ad quintum, utrum videlicet angelus possit moveri in instanti, videtur quod sic, immo quod non possit successive moveri, et hoc per rationes quas facit Philosophus, quarto Physicorum, ad probandum quod non possit aliquid moveri in vacuo. Arguit enim ibi, capitulo de vacuo, primo sic: qualis est proportio medii ad medium in densitate et raritate, talis est proportio motus ad motum in velocitate et tarditate; sed vacui ad plenum nulla est proportio in raritate et densitate; ergo nec motus facti in pleno ad motum factum in vacuo erit aliqua proportio in velocitate et tarditate. Constat autem quod ista ratio Philosophi tenet ex hoc quod medium magis vel minus resistit motori seu etiam mobili secundum quod est magis vel minus densum. Quanto enim est in medio minor resistentia, tanto motus est velocior, et econverso tanto motus tardior quanto resistentia maior.

<1> Tunc potest argui ad propositum primo sic: ubi nulla est proportio medii ad medium quantum ad resistentiam, nec est aliqua proportio motus ad motum quantum ad velocitatem et tarditatem; sed medii per quod angelus movetur ad medium per quod corpus movetur nulla est proportio quantum ad resistentiam, cum medium per quod angelus movetur nullo modo resistat angelo; ergo nec motus angeli ad motum corporis erit aliqua proportio in velocitate; ergo est in instanti.

Confirmatur, quia secundum Commentatorem ibidem, divisio sive successio non causatur in motu nisi ex vel resistentia medii ad mobile vel ex resistentia mobilis ad motorem; sed in motu angeli non est aliqua resistentia medii ad mobile nec mobilis ad motorem; ergo etc.

<2> Preterea secundo, Philosophus arguit ibi deducendo ad inconveniens, quod si fieret aliquis motus in vacuo, sequeretur quod in eodem et in equali tempore posset esse motus in vacuo et in pleno.

Consimiliter, ego ostendo quod si angelus movetur in tempore, sequitur quod aliquod corpus sensibile possit moveri in eodem et in equali tempore sicut angelus, quod tamen est impossibile. Probatio assumpti: quanto aliquod corpus est minus, tanto potest moveri in minori tempore ab eadem virtute; sed corpus quantum quodcumque est divisibile in infinitum; ergo si angelus movetur in tempore, corpus etiam. Accipio aliquod corpus, puta B. In tantum B poterit dividi quod eque velociter movebitur et in equali tempore ab eodem motore sicut ipse angelus, immo etiam in minori. Hoc autem est impossibile; ergo etc.

Dico tamen quantum ad hoc quod angelus virtute sua non potest naturaliter moveri localiter in instanti. Quod probo sic: illud quod in eodem instanti movetur de loco ad locum per medium in eodem instanti est in termino a quo et in termino ad quem; sed angelus non potest simul esse in pluribus locis sibi equalibus; ergo non potest de loco sibi equali et proportionato moveri in instanti ad alium distantem ab illo loco priori.

<-1p> Ad rationem primam in oppositum, forte posset dici uno modo quod duplex est successio, una essentialis, et ista non est ex aliqua resistentia medii ad mobile nec mobilis ad motorem, sed est ex divisione medii per quod fit motus. Alia est successio accidentalis motus penes quam attenditur velocitas et tarditas in motu. Sic enim se videntur habere velocitas et tarditas in motu sicut se habent raritas et densitas in quantitate permanente. Et ideo, sicut quantitas permanens videtur habere certum terminum quantitatis quantum ad maius et quantum ad minus — aliter non diceret Philosophus quod est dare minimam carnem et minimum os — et quod omnium natura constantium est certus terminus et magnitudo, et ita potest aliquod quantum permanens in tantum rarefieri quod non potest plus vel etiam condensari, ita etiam videtur quod licet motus possit intendi et remitti quantum ad velocitatem et tarditatem, est tamen dare terminum utrobique. Et ita diceretur quod motus angeli habet successionem absque aliqua resistentia.

<-1r> Sed tamen dico aliter sequendo Commentatorem, et concedo cum ipso quod omnis motus successivus est successivus propter aliquam resistentiam. Unde dico quod motus angeli est successivus propter resistentiam mobilis ad motorem. Ubi tamen est advertendum quod mobile resistere motori potest esse duplici de causa: uno modo aliquod mobile resistit motori ex hoc quod habet inclinationem naturalem ad aliquod ubi oppositum illi ubi ad quod movetur, sicut grave resistit moventi ipsum sursum quia habet inclinationem ad oppositum, puta ad ubi deorsum. Isto modo celum non resistit angelo moventi ipsum, quia tunc motus celi esset violentus. Alio autem modo aliquod mobile potest resistere suo motori non quia habeat inclinationem ad oppositum, sed solum quia non habet perfectam obedientiam ad ipsum. Quia enim istud mobile, quodcumque sit, non potest simul esse naturaliter in pluribus locis, ideo quando est in uno loco non potest esse in alio. Nec est in perfecta obedientia respectu alicuius agentis finiti quod possit moveri ab isto loco et poni in alio in quacumque mensura. Et sic, quando movetur ab uno loco ad alium, resistit motori, cum non sit in perfecta obedientia eius ut moveatur sive transferatur de loco ad locum in quacumque mensura.

Dico ergo quod non solum repugnantia contraria mobilis ad motorem, qualis est in motu violento propter inclinationem mobilis ad ubi oppositum, est causa successionis motus, sed etiam resistentia privativa, qualis est in quocumque motu locali cuiuscumque rei finite, sive corporalis sive spiritualis, facto a virtute

finita. Ex quo concedo quod angelus potest movere et se ipsum et alia successive et non in instanti propter rationem iam dictam, quia licet in eius motu quo movet se localiter non sit resistentia mobilis ad motorem positiva contraria, est tamen ibi, ut dictum est, resistentia privativa.

<-2p> Ad secundum, dico quod impossibile est corpus aliquod posse moveri in tam brevi tempore sicut angelus movetur. Ad probationem, quando arguitur, ‘quanto corpus est minus, tanto potest in minori tempore moveri, quia tanto minus resistit motori’, hic posset dici quod non est verum. Licet enim requiratur debita proportio inter movens et mobile, non tamen semper minus mobile potest ab eodem motore moveri citius, quia non semper minus est sibi magis proportionatum. Citius enim et facilius movet idem movens aliquem maiorem lapidem quam minimum.

<-2r> Hic tamen dico aliter, et magis ad propositum, quia quod maius mobile eadem virtus velocius et citius moveat, hoc forte provenit aliunde, videlicet ex maiori et minori resistentia medii ad mobile, vel ex aliquo alio. Et ideo dico sic: quandocumque aliqua sunt alterius rationis, quantumcumque unum augeatur in infinitum, numquam tamen propter hoc potest pertingere ad perfectionem alterius perfectioris illo secundum suam rationem specificam et formalem. Exemplum: angulus rectus et acutus sunt alterius rationis, et ideo si acutus crescat in infinitum, numquam propter hoc perveniet ad equalitatem anguli recti, nec erit sibi equalis. In proposito etiam, subtilitas corporis et subtilitas angeli sunt alterius rationis, et ideo, licet corpus quantum quanto magis rarefit, tanto fit subtilius, tamen esto quod in infinitum rarefieret, numquam adhuc ad subtilitatem angeli pervenire posset.

Tunc per hoc dico ad propositum quod corpus mobile resistit virtuti motive angeli, angelus etiam resistit sibi ipsi. Sed ista resistentia qua angelus ut mobile resistit sue virtuti motive alterius rationis est ab illa resistentia qua corpus resistit sibi ut moventi vel cuicumque alteri, et hec est minor illa. Et ideo, quantumcumque corpus diminueretur sive divideretur in infinitum, et sic eius resistentia qua resistit motori per consequens diminueretur, numquam propter hoc ista resistentia posset adequari illi. Nec corpus posset esse in illa perfecta obedientia ad motum localem respectu angeli, nec etiam respectu alicuius alterius, sicut est ipse angelus. Sic ad questionem.

Supplement to Francis of Marchia

Reportatio in primum librum Sententiarum by Francis of Marchia

Disinctio 39

Circa distinctionem 39 quero utrum in Deo sint plures vel infinite idee.

Et videtur quod non, quoniam illud quod est imperfectionis non est ponendum in Deo in quo nulla imperfectio potest esse; sed multitudo infinitarum idearum dicit imperfectionem, dicit enim confusionem sine ordine; ergo non sunt in Deo infinite idee. Sed si non sunt infinite, non oportet in eo ponere finitas nec aliquam per consequens, cum ipse intelligat infinita et ipse idee ponantur propter obiecta cognita; ergo etc.

Contra: Augustinus, in libro *83 questionum*, questione 46, "tanta," inquit, "ibi vis est in ideis ut nemo sine eis sapiens esse possit."

Item, 12 *De civitate Dei*, capitulo 18, dicit quod quamvis infinitorum non sit numerus, non est tamen apud illum incomprehensibilis infinitas numerorum cuius scientie non est numerus.

Circa istam questionem sic procedam: primo enim excludam aliquos modos dicendi; secundo dicam aliter.

[Articulus primus]

Quantum ad primum, dicitur quod in Deo sunt omnium intelligibilium distincte et proprie idee. Cuius ratio est quoniam omnis intellectus qui intelligit aliquid indiget ratione intelligendi ad intelligendum illud, per quam quidem intelligit illud; sed intellectus divinus intelligit essentiam suam et etiam omnia alia a se;

ergo oportet quod habeat rationem intelligendi se et etiam alia a se. Sed idem sub eadem ratione non potest esse ratio intelligendi immediate plura ut plura et distincta; essentia autem est formaliter unica, alia autem ab essentia, que quidem intelligit, sunt plura, immo etiam infinita; ergo preter essentiam oportet ponere in Deo rationes intelligendi proprias singulorum que intelligit.

Ad hoc etiam videtur esse intentio Augustini, *83 questionibus* ubi supra, ubi loquens de ideis sic dicit: "Idee sunt forme principales rerum stabiles atque incomprehensibiles, ac per hoc nec formate nec create sunt, sed tamen per eas formari dicitur quicquid formatur et oritur."

[Primus modus dicendi]

Et in ista conclusione concordant multi, licet diversimode. Unde iuxta hoc est hic triplex modus dicendi. Primus modus est quod idee sunt rationes intelligendi, et ideo precedunt ipsum actum intelligendi divinum in ipsa essentia formaliter existentes.

Modus autem ponendi istorum talis est: Dicunt enim quod in essentia divina correspondet propria perfectio cuiuslibet nature specifice distincta a perfectione correspondente alteri specierum, sicut aliqua perfectio propria est in divina essentia formaliter que correspondet perfectioni lapidis et alia distincta ab ista que correspondet perfectioni hominis, et sic de omnibus aliis speciebus. Tunc dicunt quod iste perfectiones in divina essentia formaliter representant perfectiones specierum quibus correspondent, et iste sunt idee ipsarum, sicut perfectio in divina essentia correspondens perfectioni hominis et ipsam representans distincte est eius idea, et sic de aliis. Ita quod secundum hoc idee non sunt nisi quedam divine perfectiones speciales in essentia divina distinctis perfectionibus creaturarum quarum sunt idee correspondentes et ipsas representantes, que quidem sunt rationes intelligendi illa obiecta que representant distincte incommutabiles et eterne.

Pro ista opinione est ratio et auctoritas Augustini. Ratio est ista: ratio intelligendi videtur esse prior ipso actu intelligendi, cum sit medium eius; sed idee sunt rationes intelligendi et sunt distincte; ergo sunt in divina essentia ante actum.

Preterea, omne quod cognoscitur cognoscitur per similitudinem aliquam; sed idem inquantum idem non potest esse similitudo plurium ut plura sunt; ergo cum divinus intellectus cognoscat plura perfecte et distincte, oportet quod habeat in essentia sua aliqua plura distincta in quibus fundetur similitudo ad diversa obiecta cognita. Ista autem non sunt aliud quam huiusmodi predicte plures perfectiones correspondentes distinctis creaturarum perfectionibus et ipsas representantes, ergo etc.

Ad hoc etiam secundo est auctoritas Augustini, *83 questionibus*, questione 48, ubi sic dicit: "Omnia sunt condita propriis rationibus. Nec enim," inquit, "eadem ratione conditus est homo qua equus." Unde concludit singula, ergo propriis sunt creata rationibus.

Preterea, 6 *De trinitate*, capitulo ultimo, loquens de verbo divino, dicit quod est ars "Dei Patris plena omnium rationum viventium et incommutabilium."

Sed iste modus dicendi non videtur esse verus. Primo, quia videtur ponere aliqua limitata in Deo formaliter. Secundo, quia videtur ponere pluritatem sine necessitate.

Primum ostendo sic: omnis perfectio representans determinate unam perfectionem tantum et non aliam est limitata in representando, et per consequens in essendo, quoniam limitatio in representando non venit nisi ex limitatione sui in essendo; sed secundum istam opinionem perfectio cuiuslibet rei, puta perfectio correspondens homini, in divina essentia representat tantum hominem et non alia, et sic de aliis perfectionibus in divina essentia correspondentibus aliis; ergo quelibet perfectio correspondens cuilibet perfectioni creaturarum in divina essentia est limitata in representando, et per consequens in essendo.

Secundum, videlicet quod ponat pluritatem sine necessitate, probatur: quoniam constat quod divinus intellectus intelligit huiusmodi perfectiones proprias quas vocat ideas, quero per quid? Aut enim intelligit eas per essentiam suam aut per seipsas. Si per essentiam suam, ergo idem sub eadem ratione potest esse ratio intelligendi plura distincta, et ita per consequens non oportet ponere ad intelligendum plura aliqua plura distincta que sint rationes intelligendi ipsa. Si autem dicas quod non per essentiam, sed per seipsas, contra, quia intellectus intelligens plura eque primo per rationes proprias intelligit ea distinctis actibus; sed intellectus divinus eodem actu numero quo intelligit se intelligit quecumque alia a se; ergo et eadem ratione intelligendi intelligit omnia. Non enim actus intelligendi potest esse magis illimitatus quam medium sive ratio intelligendi; ergo necessario unico actu semper correspondet unica ratio intelligendi, licet non econverso, quia ratio intelligendi potest esse illimitatior ipso actu, cum possit esse eadem ratio multorum actuum; ergo etc.

Confirmatur, quia actus intelligendi est similitudo obiecti expressior specie intelligibili quacumque; sed per unicam speciem non possunt representari plura sub propriis rationibus eorum; ergo nec per unicum actum possunt plura distincte intelligi per rationes proprias singulorum; ergo etc.

Preterea, non est illimitatior actus intelligendi in genere actus secundi quam essentia in genere actus primi; ergo sicut divina intellectio est unica respectu omnium intelligibilium, ita et ratio intelligendi omnia erit unica, puta essentia ipsa; ergo etc.

[Secundus modus dicendi]

Alius modus dicendi est qui ponit huiusmodi rationes intelligendi creaturas, que sunt idee, non esse in divina essentia ante actum intelligendi formaliter, ut ponit prima opinio, sed tantum ponit eas esse in ea obiective. Ante enim actum intelligendi quodlibet relucet in divina essentia propria perfectio eius, que quidem ut in divina essentia relucentes ante intellectionem cuiuscumque sunt rationes intelligendi ipsas res ut extra existentes. Et ita isti duo modi concordant in hoc, quia uterque ponit ideas esse rationes intelligendi obiecta secundaria precedentes in divina essentia intellectionem cuiuslibet. Discordant autem in hoc, quia primus modus dicendi ponit huiusmodi rationes esse in essentia formaliter, secundus autem non, sed tantum obiective.

Contra istum modum arguo sicut contra primum, quia cum intellectus divinus intelligat huiusmodi

rationes quas ponis in essentia obiective, aut intelligit eas per essentiam divinam aut per seipsas. Non per se, quia non sunt idem cum essentia, non potest autem intelligere aliquid per se quod non est idem cum essentia, quia tunc acciperet notitiam ab alio a se, et ita perficeretur ab ipso aliquo modo, quod est impossibile. Ergo per essentiam. Ergo, cum illa sint plura et ab essentia distincta, idem potest esse ratio intelligendi plura distincte. Ergo etc.

Preterea, intellectus intelligens unico actu omne intelligibile unica ratione intelligit omnia; sed intellectus divinus est huiusmodi; ergo etc. Ergo huiusmodi rationes plures ideales non sunt rationes intelligendi, cum ratio intelligendi istius intellectus sit unica numero sicut et actus eius.

[Tertius modus dicendi]

Tertius modus dicendi est quod idee sunt rationes non precedentes actum intelligendi, sed magis ipsum sequentes. Sunt enim, ut dicunt, quedam relationes rationis facte per intellectum ad ipsa obiecta secundaria, ita quod diverse idee et proprie rerum non sunt nisi diverse relationes rationis formate per intellectum ad diversa obiecta secundaria. Que quidem non sunt rationes intelligendi ipsa obiecta secundaria, immo essentia est ratio intelligendi ea, sed sunt rationes sub quibus essentia est ratio propria intelligendi quodlibet. Nec enim determinata per unam relationem rationis terminatam ad aliquid est propria ratio intelligendi illud ut per aliam aliud et sic de aliis. Dicunt enim quod essentia divina potest considerari dupliciter, quia vel in se absolute — et sic non est ratio intelligendi nisi se ipsam tantum; vel ut est sub distinctis relationibus rationis ad distincta obiecta intelligibilia secundaria — et ut sic essentia est ratio intelligendi illa, et ideo ipsa essentia est ratio intelligendi. Idee autem sunt rationes sub quibus ipsa essentia est ratio intelligendi.

Et iste modus dicendi est tripertitus. Quidem enim ponunt huiusmodi relationes rationis ad obiecta secundaria, que quidem sunt idee, esse in essentia divina per modum obiecti. Dicunt enim quod essentia divina est aliquo modo imitabilis a qualibet creatura. Et ita dicunt quod essentia ut imitabilis habet rationem idee, ut idea formaliter non sit nec dicat aliquid aliud ab essentia divina quam respectum imitabilitatis, secundum quorum diversitatem et multiplicitatem multiplicantur et plurificantur ipse idee.

Alii vero ponunt huiusmodi respectus esse in essentia divina ut ipsa habet rationem intelligendi sive ut se tenet ex parte rationis intelligendi.

Alii dicunt quod sunt sive fundantur in ipso actu intellectionis. Ut enim actus intelligendi divinus habet ad istud obiectum secundarium proprium respectum habet rationem idee respectu illius et intelligit illud per ipsum actum ut sub illo respectu.

Sed contra omnes istos tres modos arguo. Primo sic: Omnis respectus rationis presupponit terminum proprium seu obiectum; sed termini seu obiecta istorum respectuum sunt ipsa intelligibilia extra; ergo prius ordine nature divinus intellectus intelligit distincte ipsa obiecta secundaria quam ponat huiusmodi respectus rationis ad ipsa; ergo essentia non est ratio intelligendi ea sub istis respectibus, sed per se.

Confirmatur, quia intellectus non ponit huiusmodi respectus rationis nisi circa obiectum preconceptum; ergo prius natura oportet divinum intellectum obiecta secundaria preconcipere quam huiusmodi respectus rationis ad ipsa in essentia ponere. Quero tunc per quid ea intelligit? Constat quod non per essentiam sub istis respectibus, quia nondum sunt. Ergo per essentiam tantum; quare etc.

Preterea, constat quod divinus intellectus intelligit huiusmodi respectus rationis primo et distincte. Quero per quid? Aut enim intelligit eos per essentiam immediate aut per eam ut sub aliis respectibus rationis. Si primum, ergo idem potest esse ratio intelligendi plura distincte. Frustra ergo ponuntur huiusmodi plures rationes intelligendi ad hoc quod divinus intellectus distincte intelligere possit plura. Si autem per alios respectus, queram de illis, per quid eos intelligit? Et sic in infinitum.

[Articulus secundus: Opinio propria]

Et ideo dico aliter quod Deus quecumque intelligit, sive se sive alia a se, omnia intelligit immediate per essentiam suam, non per aliquid quomodocumque aliud a se. Et ideo non pono ideas ut rationes intelligendi divino intellectui alia, quia nec sic invenio quod eas posuerit Augustinus. Essentia enim absolutissime accepta sine determinatione quacumque est ratio intelligendi quecumque intelligibilia. Et ideo idee non ponuntur ut rationes intelligendi nec etiam producendi, sed ponuntur tantum propter ordinem actuum, ut inferius ostendetur.

Unde circa hoc sunt tria videnda: primo, quomodo idem sub eadem ratione potest esse ratio intelligendi plura distincte; secundo, ad quid ponuntur idee; tertio, quale esse habent idee.

[Prima quaestio secundi articuli]

Quantum ad primum ostendo hoc primo ex parte obiecti, ubi advertendum quod triplex est genus obiectorum: aliquid enim est obiectum finitum actu et potentia, ut quodlibet individuum, ut Sortes vel Plato, et tale obiectum est ratio intelligendi tantum finita actu et potentia. Aliud est infinitum in potentia, sed finitum in actu, ut quodlibet universale, saltem species que continet sub se infinita individua in potentia, et tale est ratio intelligendi infinita in potentia, modo videlicet quo ipsum est infinitum, non autem infinita in actu distincte. Tertio est aliud quod est in actu simpliciter infinitum, ut divina essentia, que est infinita in actu infinite et extra genus.

Tunc potest ex istis argui ad propositum sic: sicut se habet infinitum in potentia quantum ad hoc quod est esse rationem intelligendi infinita in potentia, ita infinitum in actu quantum ad hoc quod est esse rationem intelligendi infinita in actu; sed infinitum in potentia, puta homo vel quecumque alia species, est ratio intelligendi infinita in potentia, licet confuse et indistincte; ergo infinitum in actu simpliciter, cuius est divina essentia, potest esse ratio intelligendi distincte et perfectissime infinita in actu.

Preterea, obiectum habens unam rationem equivalentem in perfectione infinitis rationibus distinctis potest esse sufficientissime ratio intelligendi infinita intelligibilia que per illas rationes infinitas, quibus ista ratio unica equivalet, possunt intelligi — ista patet, continens enim aliqua eminenter potest esse ratio

intelligendi illa acsi ea formaliter contineret; sed divina essentia unica equivalet perfectionibus creaturarum, immo per unicam rationem supereminenter continet omnes; ergo ipsa per unicam rationem potest esse ratio intelligendi omnia.

Secundo declaro hoc idem ex parte potentie. Ubi advertendum quod nos per eandem numero potentiam sine distinctione aliqua ex parte potentie possumus successive intelligere infinita cum sola distinctione et successione actuum. Licet enim eadem potentia omnia intelligamus, tamen non eodem actu, nec eadem ratione intelligendi, sed alio et alio, et hoc est ex limitatione nostri actus intelligendi, sicut ex illimitatione potentie, quod eadem indistincta possit in infinita obiecta. Unde si nos haberemus unum actum intelligendi eque illimitatum in genere actus sicut est potentia in genere potentie, et semper stantem ut ipsa sicut erit in patria — quia ibi, secundum Augustinum, non erunt volubiles cogitationes, sed omnia unico intuitu sive actu videbimus — tunc quicquid intelligimus, intelligeremus per illum actum potentie adequatum, sicut per eandem potentiam. Nunc autem non, quia potentia est illimitatior ipso actu.

Consimiliter dico de ratione intelligendi sicut de actu, quoniam si ipsa esset eque illimitata sicut potentia, intelligeremus per unicam rationem intelligendi; sed divinus intellectus, quia illimitatior nostro, cum sit infinitus, habet in se unicum actum semper stantem sibi adequatum et eque illimitatum sicut ipse habet unicam rationem intelligendi adequatam et illimitatam, videlicet essentiam suam, que quidem est eque illimitata in ordine rationis intelligendi sicut est potentia intellectiva in ratione principii intellectivi. Ex quo patet quod sicut non oportet in Deo ponere plures actus intelligendi ad hoc ut plura distincte intelligat, ita eadem ratione nec plures rationes intelligendi, cum possit per unicam rationem sicut et per unicum actum intelligere quecumque intelligibilia distinctissime et perfecte.

[Secunda quaestio secundi articuli]

Quantum ad secundum, ubi est videndum ad quid ponuntur idee, ex quo non ponuntur sicut rationes intelligendi, ut dictum est, dico quod ponuntur propter ordinem actuum.

Ad cuius evidentiam sciendum est quod agens per intellectum habens duas vel plures operationes subordinatas, vel unam continentem duas sic subordinatas sicut habens operationem immanentem et transeuntem, vel unam utramque continentem, propter ordinem istarum, sicut operatio immanens est prior, ita prius agens habet terminum operationis immanentis quam terminum operationis transeuntis. Vel si sit idem terminus utriusque, primo habet ipsum ut est terminus operationis immanentis quam ut est terminus transeuntis. Tunc ad propositum, Deus habet circa creaturam duplicem operationem, videlicet immanentem, ut velle et intelligere, et transeuntem, sicut actum creandi, qui est quasi transiens secundum rationem, non tamen realiter magis quam operatio immanens, quia nec iste due operationes sunt, ut puto, distincte in Deo. Deus ergo propter ordinem istorum actuum predictorum prius habet terminum intellectionis quam terminum creationis. Idee autem non sunt nisi ipsa obiecta secundaria actus intelligendi ut actum ipsum terminantia, ita quod lapis ut cognitus est idea lapidis ut lapis est terminus actionis sive operationis transeuntis, puta creationis. Et ita de aliis secundariis obiectis omnibus divini intellectus, ita quod sicut operatio immanens est quasi via ad operationem transeuntem, ita terminus operationis immanentis ad terminum operationis transeuntis. Et ita idee non sunt rationes proxime intelligendi, nec rationes etiam producendi ex parte producentis, ut imaginatur quidam. Deus enim eadem

volitione qua ab eterno voluit res contingenter, illa semper stante eadem ponit res in esse pro tempore pro quo ponit.

Hec videtur esse intentio Augustini, qui dicit quod idee sunt forme rerum principales atque incommutabiles que divina intelligentia continentur, et hoc per modum obiectorum, ut dictum est, non formaliter.

Tunc secundum hoc dico quod in Deo sunt infinite idee. Quot enim sunt obiecta cognita tot sunt idee, quodlibet enim habet propriam ideam; obiecta autem cognita sunt in Deo infinita, cum cognoscat infinita; igitur etc.

[Tertia quaestio secundi articuli]

Quantum ad tertium, quale videlicet esse habeant huiusmodi idee, utrum videlicet quidditates rerum cognite ab eterno ab intellectu divino, que quidem, ut dictum est, sunt idee ipse, habeant aliquod esse distinctum ab actu intelligendi, vel sint penitus idem cum actu.

Aliqui dicunt quod non. Dicunt enim quod lapis intellectus vel volitus ut sic non est aliud ab actu divine intellectionis vel volitionis. Et hec etiam videtur esse de intentione Augustini 5 *Super Genesim*, capitulo XV, et 4 *De trinitate*. 5 enim *Super Genesim*, super illo verbo: "Quod factum est in ipso vita erat," probat Augustinus dupliciter quod ista littera non debet sic punctuari: ‘Quod factum est in ipso, vita erat’, sed sic: ‘Quod factum est, in ipso vita erat’. Cuius ratio sua prima ibi est quod primo modo punctundo videtur innui quod illud quod factum est non sit factum per ipsum, sed tantum in ipso, cum tamen omnia sint facta per ipsum et sint in ipso.

Secunda ratio sua ibi est quia tunc sequeretur quod terra vel quodcumque aliud inanimatum esset vita, cum quodlibet sit factum in ipso. Et concludit postea sic: "Ergo quod factum est, in ipso vita erat antequam fieret. Et non qualitercumque vita, quia non qualis est vita pecudum, sed que erat lux homini," hec est intellectualis; sed si creature cognite haberent esse distinctum ab ipso, constat quod quantum ad illud esse non essent vita intellectualis; ergo etc.

Preterea, secundum eundem, idee sunt forme principales, non facte seu formate, <sed> incommutabiles et eterne; constat autem quod solus Deus est talis; ergo sequitur quod quidditates rerum cognite non habent aliquod esse distinctum ab actu divine cognitionis.

Confirmatur, quia si haberent aliquod aliud esse, illud esset formatum seu constitutum per actum intelligendi seu volendi; sed secundum Augustinum, idee non sunt formate; ergo etc.

Sed contra: quia idem secundum idem non potest esse necessarium et contingens; sed actus intelligendi divinus est necessarius, cum sit idem quod Deus, esse autem intellectum vel volitum est contingens — contingenter enim Deus vult alia a se, et ita potest ea non velle nec intelligere, et ita tam esse intellectum quam volitum est contingens; ergo etc.

Preterea, que non sunt eadem inter se, nec alicui tertio; sed esse volitum et non-volitum et intellectum et non-intellectum non sunt idem inter se; ergo nec cum actu; sed quicquid extra se est volitum et intellectum potest esse non-intellectum et non-volitum; ergo etc.

Ad hoc etiam videtur esse intentio Augustini in libro *83 questionum*, questione 46, ubi dicit quod "alia ratione conditus est homo, alia equus" etc., ubi supra. Ex quo potest argui, quoniam illud quod multiplicatur non potest esse idem cum eo quod est immultiplicabile; sed actus divinus intelligendi vel volendi est unus vel unicus ipsis intellectis et volitis multiplicatis — secundum enim Augustinum ubi supra, singula singulis et suis propriis rationibus communicantur; ergo etc.

Posset dici quod habent aliquod esse distinctum ab actu. Ad cuius evidentiam posset dici quod sicut est duplex actio, videlicet transiens et immanens, ita utrisque correspondet aliquis terminus, cum nulla actio sit sine aliquo termino sibi correspondente — omnis enim actio est nata habere aliquem terminum; nunc autem intellectio et volitio in Deo sunt actiones sive operationes immanentes; ergo habent terminum aliquem accipientem esse per ipsas. Terminus autem istorum actuum non est res producta secundum esse quod habet in re extra, quoniam ut sic, secundum istud esse, res sunt terminus actionis transeuntis. Nec sunt ab eterno, sed ex tempore, cum tamen ab eterno fuerint intellecte et volite. Ergo sicut per actum creationis transeuntem obiectum capit esse simpliciter, ita etiam per actum immanentem, puta per intellectionem et volitionem, obiectum capit aliquod esse diminutum et secundum quid.

Confirmatur, quia divina intellectio maioris perfectionis est quam sit nostra; sed per intellectionem nostram, obiectum intellectum capit aliquod esse, puta esse intellectum, distinctum ab ipso actu intelligendi — quod patet, quia huiusmodi esse est obiective in intellectu, non autem isto modo est in ipso intellectio, sed tantum formaliter, nisi in intellectione reflexa; ergo etc.

Secundum hoc ergo, tenendo hoc posset dici quod esse cognitum vel volitum dicit duo. Dicit enim concretum denominativum intellectionis, et quantum ad hoc esse cognitum non differt ab actu cognitionis nisi secundum rationem, sicut nec album ab albedine vel quodcumque aliud concretum a suo abstracto. Secundo dicit substratum, quod quidem denominatur ab ipso cognitionis actu, quod quidem est esse diminutum factum vel formatum per ipsum actum cognitionis, qui fuit ab eterno, sicut et huiusmodi esse diminutum.

Ad argumentum in contrarium, ad illud Augustini, 5 *Super Genesim*, concedo quod obiectum quodcumque, antequam fieret, erat in intellectu divino vita intellectualis, et hoc participative, non formaliter et intrinsece. Obiectum enim cognitum ut obiective in actu participat aliquo modo vitam sui actus non formaliter, sed tantum obiective.

Vel potest dici aliter quod obiectum ab eterno habuit duplex esse in Deo, sive dupliciter fuit in eo. Fuit enim in ipso virtualiter, et quantum ad istud esse, videlicet virtuale, obiectum intellectum et actus sunt omnino idem, quia huiusmodi esse virtuale non est nisi ipse Deus a quo non distinguitur ipse actus. Nec quantum ad istud esse res sive rerum quidditates factibiles sunt in potestate Dei, sicut nec ipse Deus. Licet enim Deus posset ponere et non ponere divisim res in esse, et per consequens sit in eius potestate

producere vel non producere circa eas, non tamen posse producere. Licet enim contingenter producat, necessario tamen potest eas producere. Et isto modo, puta quantum ad huiusmodi esse virtuale, videtur loqui Augustinus, 6 *De trinitate*, ubi dicit quod filius est ars "Dei patris plena omnium rationum vivientium." Et subdit ibi quod omnes huiusmodi rationes sunt "in ea unum <sicut> unum de uno."

Alio autem modo obiectum habet esse in Deo, videlicet intentionaliter seu obiective. Et isto modo habet esse aliquod distinctum ab actu. Et hoc modo quantum ad istud esse loquitur Augustinus in libro *83 questionum*, questione 46, ubi supra, quando dicit quod "non eadem ratione conditus est homo qua equus," etc. Et ita Augustinus videtur innuere quod est duplex genus intentionum sive rationum. Sunt enim quedam virtuales, alie obiective, sive quod quidditates rerum habent duplex esse, videlicet virtuale et obiectivum. Secundum esse virtuale non sunt formate per actum aliquem, sed sunt idem quod actus, et ita ut sic dicit quod sunt incommutabiles et eterne et unum. Secundum autem esse obiectivum sunt formate per actum, et quantum ad tale esse dicit quod "non eadem ratione conditus est homo qua equus."

Tunc ergo secundum hoc potest dici quod quelibet creatura, antequam fieret, in illo vita erat formaliter, et hoc quantum ad esse virtuale. Erat etiam vita non formaliter, sed participative obiective, sive quantum ad esse obiectivum.

Ad illud quod dicitur, quod sunt incommutabiles etc., dico quod verum est quantum ad esse virtuale, non autem quantum ad esse obiectivum, puta quantum ad esse intellectum vel volitum. Immo quantum ad istud esse sunt contingentes, et in tali esse contingenter posite seu formate. Sic ad questionem.

[Ad argumentum principale]

Ad rationem in principio, quando dicitur quod non est ponendum in Deo aliquid quod sit imperfectionis, concedo. Sed tunc nego minorem. Infinitas enim idearum eo modo quo dictum est superius ipsam esse in Deo non dicit imperfectionem.

Ad probationem, dico quod ista multitudo non dicit confusionem sine ordine, immo est ibi ordo perfectionis, cum omnes ad rationem essentie reducantur.

Distinctiones 42-44

Circa distinctiones 42, 43, et 44 quero primo utrum ratio possibilitatis et ratio impossibilitatis creature sumatur ex parte Dei vel ex parte creature.

Videtur primo quod ex parte creature, quoniam a puro actu non potest accipi ratio potentie, nec etiam ratio opposita rationi potentie, cuius est ratio impossibilitatis; sed Deus est actus purus; ergo, etc.

Contra, quia ratio habentis causam magis debet sumi ex prima causa quam a secunda; omnis possibilitas et impossibilitas rei habent causam aliquam possibilitatis et impossibilitatis; ergo ratio cuiuslibet debet accipi ex parte Dei, qui est omnium prima causa.

Circa istam questionem primo videndum est quomodo Deus sit omnipotens; secundo, unde sumatur possibilitas et impossibilitas quarumdam rerum secundum quam dicimus quod Deus non potest peccare vel mentiri et huiusmodi.

[Articulus primus]

Quantum ad primum dico quod omnipotens est qui potest in omne possibile. Ad cuius evidentiam sciendum est quod possibile sumitur dupliciter. Uno enim modo accipitur ut distinguitur contra impossibile, et sic isto modo omne necessarium est possibile, quia non est impossibile -- immo necessarium est maxime possibile isto modo, quia ita est possibile quod nullo modo potest non esse. Unde isto modo possibile non opponitur necessario, sed opponitur contradictorie impossibili. Alio modo accipitur possibile ut distinguitur contra necessarium, secundum quod possibile est cui non repugnat esse et non esse, quia potest esse et non esse. Necessarium autem est cui repugnat non esse.

Tunc dicunt aliqui quod possibile quod est obiectum omnipotentie est possibile sumptum secundo modo, non autem primo modo, videlicet non ut dividitur contra impossibile, sed tantum ut dividitur contra necessarium, ut omnipotens dicatur qui potest in omne possible -- sit possibile quod potest esse et non esse. Et hoc est commune tribus personis, cum quelibet possit in quodcumque possibile isto modo.

Sed tamen dico aliter quod obiectum omnipotentie est quodcumque aliud ab omnipotente, sive sit possibile sive necessarium. Unde dico quod omnipotens est qui potest in omne aliud a se. Nihil enim potest in se ipsum. Et in hoc conveniunt omnes tres persone divine. Quelibet enim potest in quodcumque aliud a se, licet non in quodcumque alium a se masculine. Filius enim non est aliud a Patre, secundum Augustinum, sed tantum alius. Idem de Spiritu Sancto. Et ideo, quia in quodcumque aliud potest una personarum, potest alia, licet non in quemcumque alium. Idcirco omnes tres persone sunt omnipotentes et unum omnipotens.

Hoc de primo.

[Articulus secundus]

Quantum ad secundum, sunt tres modi dicendi. Primus modus dicendi est quod aliter est loquendum de causa possibilitatis et aliter de causa sive ratione impossibilitatis, quoniam possibilitas dicit aliquo modo perfectionem. Omne enim possibile ut sit, dicitur aliquo modo ens, et ita dicit perfectionem. Impossibilitas autem dicit imperfectionem, quoniam impossibile est non ens. Secus autem est dicendum de hiis que includunt perfectionem et secus de eo quod includit imperfectionem, quoniam omne includens vel dicens perfectionem aliquam habet primo ortum a Deo quam a creatura. Omnis enim perfectio et omne bonum primo est a Deo quam ab aliquo alio. Illud autem quod dicit imperfectionem et defectum non habet primo ortum a Deo, sed a creatura. Quia ergo possibilitas dicit bonum et perfectionem, ideo dicunt quod ratio possibilitatis est primo ex parte Dei, non autem ex parte creature. Sed quia per oppositum impossibilitas dicit imperfectionem, ideo etiam per contrarium ratio impossibilitatis sumitur primo ex parte creature, non ex parte Dei. Unde dicunt quod ideo hoc est possibile fieri quia Deus est

potens illud facere; non autem e converso Deus potest hoc facere quia ipsum est possibile fieri. Ita quod potentia vel potestas Dei activa est ratio possibilitatis creature passive. De impossibilitate autem est contrarium, quoniam ideo Deus non potest hoc facere quia hoc est impossibile fieri; non autem e converso quia hoc Deus non potest facere ideo hoc est impossibile fieri. Ita quod ratio impossibilitatis sumitur primo ex parte creature et ratio possibilitatis ex parte Dei.

Pro ista opinione arguitur, quia quicquid perfectionis est in creatura venit primo ex parte Dei, sic et quicquid est imperfectionis venit ex parte creature; sed esse possibile est perfectionis; esse autem impossibile est imperfectionis; ergo etc.

Contra, quia in causis precisis, si affirmatio est causa affirmationis, et negatio est causa negationis, secundum Philosophum in primo *Posteriorum*; sed secundum istam opinionem, quia Deus potest aliquid facere, ideo illud est possibile; ergo negatio illius affirmationis, que est quod Deus non potest hoc facere, erit causa quare illud sit impossibile fieri, que est consimiliter negatio illius affirmationis cuius illa affirmatio erat causa; ergo si prima ratio possibilitatis est ex parte Dei, erit etiam et prima ratio impossibilitatis.

Preterea, illud quod est posterius numquam potest esse causa prioris; sed si possibilitas ex parte Dei est causa possibilitatis ex parte creature, negatio possibilitatis ex parte Dei erit prior negatione possibilitatis ex parte creature. Probatio: Quia in negationibus disparatis, cuius sunt iste, negatio prioris affirmationis est prior negatione posterioris affirmationis; sed possibilitas ex parte Dei est prior possibilitate ex parte creature, cum sit per te causa eius; ergo et negatio eius erit prior negatione illius; ergo negatio possibilitatis sive impossibilitas creature non est causa impossibilitatis Dei, cum sit posterior ea, ut probatum est.

Alius modus dicendi est quod ratio utriusque, videlicet tam possibilitatis quam impossibilitatis, sumitur ex parte Dei. Ideo enim aliquid est possibile fieri quia Deus potest illud facere, et ideo impossibile quia non potest Deus illud facere; non autem e converso.

Et si queratur quare Deus hoc non potest facere, hic est status. Non enim dicendum est quod ideo non potest quia est impossibile, quia tunc sic dicendo esset | circulus in causis, cum hoc ponatur impossibile quia Ipse non potest illud facere, sed non potest quia hoc non sibi convenit, <quia> hoc posse non est posse.

Sed contra hoc arguo, quia nihil est impossibile nisi quod includit contradictionem, quia omne non includens contradictionem est possibile. Secundum quod aliqua includant contradictionem vel non includant, hoc non est ex parte Dei, sed ex parte terminorum. Deo enim per impossibile non existente, homo et non homo includerent contradictionem et repugnantiam, et homo et animal non includerent. Ergo ratio possibilitatis vel impossibilitatis venit non ex parte Dei, sed ex ratione intrinsica terminorum.

Tertius modus dicendi est quod quecumque possibilia vel impossibilia sunt possibilia vel impossibilia non ex parte Dei nec ex aliquo intrinsico, sed ex natura terminorum. Quod enim homo et album sint possibilia,

hoc est ex natura ipsorum, puta quia homo est homo et album est album. Quod etiam homo et non homo sint impossibilia, hoc est ex natura terminorum, quia videlicet homo est homo, etc.

Contra hoc arguo, quia si termini sunt causa possibilitatis et impossibilitatis opposite, quero in quo genere cause universalis istius impossibilitatis qua est impossibile quod homo sit lapis? Quero in quo genere cause isti termini ‘homo’ et ‘lapis’ sunt causa eius? Aut enim sunt causa eius in genere cause materialis aut formalis aut efficientis aut finalis. Non formalis, quia lapis et homo non contradicunt formaliter, sed sunt quedam disparata. Nec materialis, quia omnis causa materialis reducitur ad causam effectivam. Materia enim per se non habet effectum sine efficiente. Ergo si termini ponantur causa huius impossibilitatis in genere cause materialis, vel quicquid aliud ponatur causa isto modo, oportet quod reducatur ad aliquid quod sit causa in genere cause efficientis. Talis autem est Deus. Cuiuscumque enim effectus Deus est causa efficiens principalis.

Si autem dicas quod in genere cause efficientis, idem sequitur, puta quod Deus sit principalior et nobiliori modo causa huius impossibilitatis seu repugnantie. Quodcumque enim aliud a Deo ponatur causa effectiva alicuius, semper Deus est illius causa principalior in genere sive ordine cause efficientis.

Dico tamen quod quelibet predictarum opinionum est vera si bene intelligatur. Ad cuius evidentiam sciendum est quod potentia est triplex, sive tripliciter accipitur. Uno enim modo potentia accipitur pro eo quod est principium entis, et isto modo accipitur a Philosopho, secundo *De anima* et 8 *Metaphysice*. In secundo enim *De anima* dicit Philosophus quod ideo ex anima et corpore fit per se unum quia unum est in potentia et aliud in actu. Idem sententialiter dicit in 8 *Metaphysice*. Hoc etiam modo loquitur de potentia Commentator in *De substantia orbis*, ubi dicit quod materia substantiatur per posse. Et ad istum modum potentie reducitur modus potentie active et passive, de quo Philosophus loquitur 8 et 9 *Metaphysice*, dicens diffiniendo potentiam activam quod potentia activa est principium transumendi aliud in quantum aliud et passiva principium transumendi ab alio. Differt tamen ista potentia a prima, quoniam prima potentia est principium entis per modum partis. Totum enim est principium componentis*. Ista autem secunda, videlicet activa et passiva, est principium entis non per modum partis sed per modum agentis et pacientis. Activa enim est principium per modum agentis et passiva per modum pacientis.

Alia est potentia que nec est principium per modum partis nec per modum agentis vel pacientis, sed est differentia entis accidentalis vel essentialis, et hec est potentia que est actu dividens ens, secundum quod dicitur quod omne quod est vel est ens in actu vel in potentia. Et ista potentia non est eadem cum prima, quoniam prima stat simul cum suo actu contra quem dividitur. Nec sibi repugnant, cum constituat unum per se cum eo in quo, ut in quodam effectu communi utriusque est simul utuumque. Illa autem potentia que est differentia entis non potest esse simul cum actu condiviso sibi. Et de ista potentia loquitur Philosophus, 8, 9, et 12 *Metaphysice*, dicens quod illud idem quod est primo in potentia postea est in actu. Commentator etiam, super 12* *Metaphysice*, de ista potentia loquens, dicit quod transumptio non largitur mere multitudinem sed perfectionem. Ista etiam potentia differt in hoc a prima quoniam prima potentia non est semper in eodem genere cum actu suo, sicut subiectum quod est in potentia passiva respectu accidentis est alterius generis ab ipso. Ista autem secunda potentia que est differentia entis est semper eiusdem generis et etiam eiusdem speciei cum actu suo. Eadem enim albedo que prius fuit in potentia postea est in actu.

Tertia potentia est que nec est principium nec differentia entis, sed est tantum modus compositionis, ut illa potentia de qua loquitur Philosophus in primo *Periarmenias*, quando dicit quod possibile est hominem currere et possibile est hominem non currere. Huiusmodi enim potentia non est nisi modus quidam compositionis predicamenti cum subiecto. Et ista potentia est potentia logica.

Nunc autem inter huiusmodi dictas tres potentias est ordo, quoniam potentia que est differentia entis supponit potentiam que est principium entis, non e converso. Potentia enim que est principium entis non presupponit potentiam que est differentia entis. Sed potentia tertia, que videlicet est tantum modus compositionis, neutram potentiam presupponit, videlicet nec illam que est principium nec etiam secundam que est differentia entis, sed est potentia que sequitur quoscumque terminos ex natura terminorum. Et ideo generatio naturalis et creatio distinguntur per hoc quoniam generatio presupponit duplicem potentiam, quia tam potentiam que est principium entis quam etiam illam que est differentia. Presupponit enim generale esse in potentia, et ita potentiam que est differentia entis et etiam potentiam subiectivam termini generationis. Et ista est principium entis. Creatio autem neutram presupponit. Nec enim presupponit illam que est principium entis nec illam que est differentia entis, sed tantum presupponit potentiam tertiam, videlicet illam que est modus compositionis, sicut creatio celi presupponit ipsum celum esse creabile. Celum autem esse creabile non est ipsum celum habere potentiam que est principium seu differentia entis, sed tantum celum esse creabile est ipsum creari fore possibile, que quidem possibilitas non est aliud quam modus sive modificatio propositionis.

Ex istis patet falsitas opinionis eorum qui ponunt quod si materia poneretur sine forma, quod tunc non haberet aliquem actum, quoniam, licet non haberet aliquem actum oppositum potentie que est principium entis, haberet tamen actum oppositum potentie que opponitur impossibili sive impossibilitati. Impossibile enim privat omnem actum, quo tamen non esset privativa universaliter materia posita sine omni forma. Solum enim esset privativa actu opposito potentie que est principium entis et etiam potentie que est differentia. Non autem actu opposito impossibilitati.

Nunc ad propositum dico quod si loquamur de illa potentia que est principium entis vel etiam de illa que est differentia entis, dico quod utraque istarum est simplex et incomplexa, et utraque venit ex potentia Dei activa -- non autem ex parte creature, quia utraque istarum sequitur creationem. Loquendo autem de potentia tertia, que requiritur et presupponitur in creatione, qua quidem creabile non fuit impossibile sed possibile creari, dico quod ista venit tam ex parte terminorum quam etiam aliquo modo ex causa extrinseca, videlicet ex parte Dei. Ubi advertendum quod dupliciter potest intelligi aliquid esse causam complexionis terminorum. Aliquid enim est causa complexionis aliquorum terminorum per modum complexi, sicut complexio principiorum sive premissarum est causa sive ratio complexionis conclusionum. Aliquid etiam secundo est causa complexionis non isto modo, sed simpliciter et modo incomplexo, sicut intellectus dicitur esse causa veritatis et complexionis conclusionis quam infert effective ex premissis et ipsarum etiam premissarum.

Tunc ex hoc ad propositum dico quod istius possibilitatis, qua quidem dicitur celum possibile esse, est causa, licet diversimode, tam Deus quam etiam termini huius complexionis, puta celum ibi esse. Termini enim sunt causa per modum complexionis istius possibilitatis sive non repugnantie. Deus autem, qui est

ens incomplexum, est causa tam non repugnantie sive possibilitatis quam etiam ipsius complexionis per modum incomplexi. Sunt tamen alique complexiones in Deo que sunt cause aliarum per modum complexi, ut quia Deus agit ideo passum patitur, sicut quia non agit ideo non patitur paciens, ita quod complexio affirmativa est causa veritatis complexionis affirmative et negativa negative. Sic ergo dico quod Deus est causa per modum incomplexi terminorum et complexionis eorum et etiam cuiuscumque possibilitatis et impossibilitatis ipsorum.

Et ita dico quod possibilitas et impossibilitas accipiuntur tam ex parte terminorum quam etiam ex parte Dei diversimode, ut dictum est.

Ex quo patet quod vera est illa opinio que dicebat quod possibilitas et impossibitas rei sumuntur ex rationibus terminorum.

Vera etiam est illa alia que dicebat quod ex parte Dei.

Per hoc etiam patet ad omnes rationes factas in oppositum.

Distinctiones 45-48

[Quaestio prima]

Circa distinctiones 45, 46, 47, et 48, quero primo utrum voluntas Dei semper impleatur.

Videtur quod sic, quia "Omnia quecumque voluit, Dominus fecit," etc.

Contrarium habetur ubi dicitur, "Quotiens volui congregare filios tuos, quemadmodum gallina congregat pullos suos et noluisti."

Ad istam question respondet Augustinus, et est in *Enchiridion*, capitulo 61, et Anselmus in libro *Cur Deus homo*, dicentes ambo quod semper voluntas Dei impletur. Licet enim aliquando videatur impediri uno modo, impletur tamen alio modo.

Ad cuius evidentiam distinguit Anselmus triplicem actum divine voluntatis, quod est intelligendum non ex parte actus, cum sit unicus in se, sed tantum ex parte obiecti. Sicut enim in nobis actus voluntatis est triplex -- est enim quidam quo voluntas aliquid imperat vel consulit, et iste est actus imperandi aliquid affirmative vel negative vel annuendi; alius est actus renumerandi sive reddendi bonum pro obediente et consilio assentiente, vel malum pro non obediente nec consilio assentiente; tertius actus est actus permittendi fieri bonum vel malum cum posset ne fieret prohiberi -- ita consimiliter ex parte divine voluntatis correspondet predicto triplici actui: Unus actus qui quidem, licet in se sit indistinctus et unicus, distinguitur tamen ex parte obiecti isto triplici modo dicto, quoniam aliquid Deus precipit affirmative ut fiat, sicut illud: "Honora patrem tuum," etc., vel negative ut non fiat, sicut illud: "Non furaberis," etc. Omnia enim precepta sunt affirmativa vel negativa; aliquid etiam consulit, ut illud: "Si vis perfectus esse,

vade et vende," etc. Secundo habet alium actum non per modum precepti nec per modum consilii, sed per modum reddendi, sive actum qui est reddere bonum bonis et malum malis. Et iste actus est actus iustitie.

Tertius eius actus est actus permittendi, quo quidem permittit malum fieri, quod tamen posset si vellet ne fieret impedire. Unde secundum Augustinum hec est ratio quia plures sunt mali quam boni, quia quanto plures sunt mali tanto magis Dei misericordia relucet in bonis qui preservantur a malis. Plusquam enim primus homo, qui pro se et aliis hominibus iustitiam acceperat, peccavit, omnes sumus facti una massa peccati. Propter quod, ut ait Augustinus, non nullus liberaretur nec a malo preservaretur nec posset conqueri. Quod autem nunc aliqui et pauci liberentur, hoc est ex maxima et summa Dei misericordia.

Tunc ad propositum, ad videndum quomodo voluntas Dei semper impleratur, Anselmus ponit quoddam exemplum de terra. Dicit enim quod consimiliter se habet creatura rationalis respectu Dei sive voluntatis eius sicut se habet terra respectu celi, quoniam sicut terra, que est in medio celi, continetur undique a qualibet parte celi, ita quod quanto magis recedit ab una parte celi tanto magis appropinquat ad aliam, nec potest ab una recedere quin ad aliam appropinquet, ita consimiliter creatura rationalis concluditur undique voluntate et omnipotentia Dei. Et ideo si vis fugere voluntatem Dei iubentem, statim incideris in voluntatem eius punientem, transeundo per voluntatem eius permittentem, et ita incideris in peius.

Ex quo concludit Anselmus, sicut et potest concludi, quod voluntas Dei semper impleretur, puta vel voluntas iubens vel puniens vel permittens. Sicut enim in contradictione semper altera pars est vera, non utraque, ita de divina voluntate semper vel impleretur ista vel illa voluntas, videlicet iubens vel puniens, licet non omnes simul. Unde ista sunt opera eius magna et exquisita in omnes voluntates eius ut nullus possit transire nec subterfugere eius voluntatem. Et ideo dicebat Psalmus, "Si ascendeo in celum tu illic es; si descendeo in infernum ades. Si sumpsero pinnas diluculo," etc.

Tunc ergo sumendo dicta sanctorum ad istam questionem et reducendo ea ad formam, quando queritur utrum voluntas Dei semper impleratur, dico quod voluntarium est triplex, ut in precedentibus dictum fuit: Est enim quoddam voluntarium permixtum cum involuntario, aliud permixtum cum non voluntario, tertium simpliciter impermixtum.

Secundum hoc dico quod, licet actus divine voluntatis sit secundum se indistinctus et unicus, tamen ex parte obiecti distinguitur, quoniam ad aliquid se habet per modum voluntarii permixti cum involuntario, ad aliquid per modum voluntarii permixti cum non voluntario, et tertio ad aliquid per modum voluntarii simpliciter et totaliter impermixti.

Ex hoc respondeo ad questionem. Et dico quod voluntas sive velle Dei permixtum cum involuntario non semper impletur, nec etiam velle permixtum cum non voluntario, cuiusmodi est illud de quo dicitur, "Quotiens volui congregare filios tuos et noluisti." Voluntas autem Dei sive velle simpliciter et totaliter impermixtum semper impletur, et de ista loquitur Psalmus, "Omnia quecumque voluit, Dominus fecit," et Apostolus dicens, "Voluntati eius quis resistet?"

Ad argumenta patet.

[Quaestio secunda]

Secundo quero iuxta hoc utrum teneamur conformare voluntatem nostram divine voluntati in quocumque volito vel nolito ab ipsa.

Hic ad istam questionem respondetur communiter et bene, si bene intelligatur, distinguendo de voluntate Dei. Dicitur enim quod duplex est voluntas Dei, intelligendo semper ex parte obiecti: Quedam enim est voluntas signi, alia vero est voluntas beneplaciti. Voluntas quidem signi est illa que explicatur per signum, puta per consilium aliquod vel preceptum, sive expresse et explicite sive implicite. Voluntas autem beneplaciti est voluntas secreta, qua quidem Ipse vult aliquid, quod tamen nobis non innotescit exterius per aliquod signum, videlicet consilium vel preceptum.

Tunc dicitur quod nos tenemur conformare nos sive voluntatem nostram divine voluntati, loquendo de voluntate signi. Debemus enim facere et tenemur ad illud quod precipit, esto etiam quod Ipse illud non velit voluntate beneplaciti quod bene interdum contingit, videlicet quod Deus aliquid precepit quod tamen fieri noluit; ut patet de Abraam cui precepit ut immolaret filium suum, quod tamen non volebat voluntate beneplaciti, sicut patuit postea per effectum. Et tamen hoc non obstante, Abraam tenebatur obedire ex quo sibi precipiebatur.

Sed contra istam distinctionem de voluntate signi et beneplaciti arguo. Videtur enim quod contradictionem includat nisi sane intelligatur. Et arguo sic: Omne signum non concordans signato est falsum; sed si est aliquid volitum voluntate beneplaciti quod non sit volitum voluntate signi, illud signum non concordat signato, immo discordat ab eo; ergo huiusmodi voluntas signi est falsa.

Et ideo dico aliter. Ad cuius evidentiam sciendum est quod in Deo, ut sepe dictum est, est triplex voluntarium: Quoddam simpliciter et totaliter impermixtum, ut illud quo Deus vult salvare bonos sive electos. Aliud est permixtum cum non-voluntario, hoc est, cum negatione alicuius gradus voluntarii. Et isto voluntario sic permixto Deus vult generaliter et indifferenter omnes salvare. Omnibus enim vult beatitudinem, non tamen perfecte seu intense, cum non removeat omne impedimentum ad hoc in omnibus, quod tamen posset facere si vellet. Et ideo ratione impedimenti quod non removet, cum tamen removere posset, velle divinum quo eis vult beatitudinem non est efficax seu intensum, immo remissum, et ideo cum non-voluntario mixtum.

Tertium est voluntarium permixtum cum involuntario, cuiusmodi est illud quo Deus vult dampnare malos seu reprobos. Et hoc involuntarium superat voluntarium propter illorum malitiam, sicut cum aliquis propter periculum tempestatis proicit merces in mari. Talis quidem vult proicere et non vult. Unde habet simul actum volendi et nolendi respectu diversorum. Vult enim proicere propter periculum iminens tempestatis; non vult autem propter preciositatem mercium. Et tamen hoc involuntarium cui voluntarium est admixtum superat voluntarium.

Consimiliter dico de Deo quantum ad velle dampnare malos. Deus enim ab eterno previdit eos sicut et alios ad sui similitudinem et imaginem esse futuros. Et ideo ordinavit eos ad beatitudinem ut ad proprium

eorum finem, et voluit eis ipsam. Tamen quia previdit alios perseverare debere in malitia, ideo ratione huius, eius velle fuit permixtum cum involuntario, quia noluit eos salvare, sed dampnare, quod quidem <est> involuntarium, superavit voluntarium ratione malitie finalis ipsorum.

Tunc ad propositum, respondeo. Ad questionem dico quod nos tenemur conformare voluntatem nostram voluntati divine quantum ad illud quod nobis est notum Deum velle, non autem quantum ad aliud. Et hinc est quod, cum velle sive voluntarium totaliter impermixtum, quo Deus vult electos salvare, sit nobis ignotum -- ignotum enim est nobis qui sunt illi quos tali actu impermixto vult ad beatitudinem pervenire -- cum etiam non solum istud voluntarium totaliter impermixtum, sed etiam illud quod est permixtum cum involuntario, quo quidem reprobos vult dampnare, sit consimiliter nobis ignotum, per consequens dico quod non tenemur conformare sive conformiter velle voluntati divine nec quantum ad velle sive voluntarium simpliciter impermixtum nec etiam quantum ad permixtum cum involuntario. Nullus enim tenetur ad impossibile; velle autem conformiter aliqui quantum ad illud quod mihi non est notum ipsum velle est impossibile. Nunc autem in vita ista non est nobis certum quid est a Deo volitum isto duplici voluntario.

Exemplum: Deus voluit filium suum mori, licet non per Iudeos. Esto etiam quod Deus voluisset Iudeos Christum occidere, ipsi tamen non tenebantur eum occidere, immo peccassent occidendo eum cum eos hoc Deum velle lateret.

Et ideo per oppositum, quia velle sive voluntarium quo Deus vult medio modo illud, videlicet quod nec est totaliter impermixtum nec etiam permixtum cum involuntario, sed tantum cum non-voluntario, quo quidem vult omnibus beatitudinem, est nobis ex scriptura certum, ideo quantum ad hoc tenemur conformare voluntatem nostram voluntati divine et conformiter velle ei nulli malum volendo, sed cuilibet eternam beatitudinem ut communem finem omnium appetendo, ad quem Ipse nos producat, qui est benedictus in secula secolorum. Amen. Amen. Amen.

Explicit lectura fratris Francisci de Marchia super primum, secundum reportationem factam sub eo tempore quo legit Sententias Parisius, anno Domini MCCCXX.

Return to Francis of Marchia

Dante Alighieri

Dante's engagement with philosophy cannot be studied apart from his vocation as a writer, in which he sought to raise the level of public discourse by educating his countrymen and inspiring them to pursue happiness in the contemplative life. He was one of the most learned Italian laymen of his day, intimately familiar with Aristotelian logic and natural philosophy, theology (he had a special affinity for the thought of Albert the Great and Thomas Aquinas), and classical literature. His writings reflect this in its mingling of philosophical and theological language, invoking Aristotle and the neo-Platonists side by side with the poet of the psalms. Like Aquinas, Dante wished to summon his audience to the practice of philosophical wisdom, though by means of truths embedded in his own poetry, rather than mysteriously embodied in scripture.

1. Life

Dante was born in 1265 in Florence. At the age of 9 he met for the first time the eight-year-old Beatrice Portinari, who became in effect his Muse, and remained, after her death in 1290, the central inspiration for his major poems. Between 1285, when he married and began a family, and 1302, when he was exiled from Florence, he was active in the cultural and civic life of Florence, served as a soldier and held several political offices.

Since the early thirteenth century two great factions, the Guelfs and the Ghibellines, had competed for control of Florence. The Guelfs, with whom Dante was allied, were identified with Florentine political

autonomy, and with the interests of the Papacy in its long struggle against the centralizing ambitions of the Hohenstaufen emperors, who were supported by the Ghibellines. After Charles of Anjou, with the blessing of the Papacy and strong Guelf support, defeated Hohenstaufen armies at Benevento (1265/6) and Tagliacozzo (1268), the Guelfs became the dominant force in Florence. By the end of the century, the Guelfs were themselves riven by faction, grounded largely in family and economic interests, but determined also by differing degrees of loyalty to the papacy and to Guelf allegiances.

In 1301, when conflict arose between the "Blacks," the faction most strongly committed to Guelf and papal interests, and the more moderate Whites, Pope Boniface VIII instigated a partisan settlement which allowed the Blacks to exile the White leadership, of whom Dante was one. He never returned to Florence, and played no further role in public life, though he remained passionately interested in Italian politics, and became virtually the prophet of world empire in the years leading up to the coronation of Henry VII of Luxemburg as head of the Holy Roman Empire (1312). The development of Dante's almost messianic sense of the imperial role is hard to trace, but it was doubtless affected by his bitterness over what he saw as the autocratic and treacherous conduct of Pope Boniface, and a growing conviction that only a strong central authority could bring order to Italy.

During the next twenty years Dante lived in several Italian cities, spending at least two long periods at the court of Can Grande della Scala, lord of Verona. In 1319 he moved from Verona to Ravenna, where he completed the *Paradiso*, and where he died in 1321.

Dante's engagement with philosophy cannot be studied apart from his vocation as a writer -- as a poet whose theme, from first to last is the significance of his love for Beatrice, but also as an intellectual strongly committed to raising the level of public discourse. After his banishment he addressed himself to Italians generally, and devoted much of his long exile to transmitting the riches of ancient thought and learning, as these informed contemporary scholastic culture, to an increasingly sophisticated lay readership in their own vernacular.

This project was Dante's contribution to a long-standing Italian cultural tradition. His reading in philosophy began, he tells us, with Cicero and Boethius, whose writings are in large part the record of their dedication to the task of establishing a Latinate intellectual culture in Italy. The *Convivio* and the *De vulgari eloquentia* preserve also the somewhat idealized memory of the Neapolitan court of Frederick II of Sicily (1195-1250) and his son Manfred (1232-66), intellectuals in their own right as well as patrons of poets and philosophers, whom Dante viewed as having revived the ancient tradition of the statesman-philosopher [Van Cleve, 299-332; Morpurgo]. Dante himself probably studied under Brunetto Latini (1220-94), whose encyclopedic *Livres dou Tresor* (1262-66), written while Brunetto was a political exile in France, provided vernacular readers with a compendium of the Liberal Arts and a digest of Aristotelian ethical and political thought [Meier; Imbach, 37-47; Davis (1984), 166-97].

But the fullest medieval embodiment of Dante's ideal is his own writings. In them we see for the first time a powerful thinker, solidly grounded in Aristotle, patristic theology, and thirteenth-century scholastic debate, bringing these resources directly to bear on educating his countrymen and inspiring them to pursue the happiness that rewards the philosopher.

2. Early Poetry

Though he evidently did not begin serious study of philosophy until his mid-twenties, Dante had already been intellectually challenged by the work of a remarkable group of poets, practitioners of what he would later recall as the *dolce stil novo*, in whose hands a lyric poetry modelled on the *canso* of the Provençal troubadours became a vehicle for serious enquiry into the nature of love and human psychology. A generation earlier Guido Guinizzelli (1230-1276) had puzzled contemporaries with poems treating love in terms of the technicalities of medicine and the cosmology of the schools, while celebrating in quasi-mystical language his lady's power to elevate the spirit of her poet-lover:

> *Splende in la intelligenzïa del cielo*
> *Deo crïator, più che 'n nostri occhi 'l sole;*
> *ella intende suo fattor oltra 'l cielo,*
> *e 'l ciel volgiando, a lui obedir tole;*
> . . .
> *così dar dovria, al vero,*
> *la bella donna, poi che 'n gli occhi splende*
> *del suo gentil, talento,*
> *chi mai da lei obedir non si disprende.*
>
> [*Al cor gentil rempaira sempre amore*, 41-44, 47-50]
>
> Translation:
> God the creator shines in the intelligence of heaven more than the sun in our eyes, and this [intelligence] understands her maker beyond the universe. Making the heavens turn, she submits to obey Him . . . So truly should the beautiful lady, when she shines on the eyes of her gentle [lover], impart the desire that his obedience to her never fail.

The Lady, exerting on her lover a power derived from the participation of her understanding in the divine, plays the role of the celestial *intelligenze*, who transmit the influence of the First Mover to the universe at large. The poet is thus caught up in a circular process through which his understanding, like theirs, is drawn toward the divine as manifested in the lady's divinely inspired radiance. For Guinizelli this exploitation of the idea of celestial hierarchy is perhaps only a daring poetic conceit. For Dante it will become a means to the articulation of his deepest intuitions.

Guido Cavalcanti, Dante's older contemporary and the single strongest influence on his early poetry, was renowned not only as a poet, but for his knowledge of natural philosophy. His great *canzone*, "*Donna mi prega*," which became the subject of learned Latin commentaries, deals with ideas commonly associated with the "radical Aristotelianism" or "Averroism" of his day. The purpose of this astonishing poem is to describe in precise philosophical terms ("*naturale dimostramento*") the experience of love.

For Guido there is an absolute cleavage between the sensory and intellectual aspects of the response to a loved object. Once the phantasma of the object becomes an abstracted form in the possible intellect, it is wholly insulated from the *diletto* of the *anima sensitiva* (21-28). This has seemed to modern commentators to imply an Averroist view of the intellect as a separate, universal entity [Corti (1983), 3-37], and the lines which follow (30-56), where the *vertú* of the sensitive soul displaces reason and "assumes its function," presenting to the will an object whose desirability threatens a fatal disorientation, sustain this impression. Love is still the aristocratic vocation of the troubadours, and Guido acknowledges that noble spirits are aroused by it to prove their merit. But they work in darkness, for the force that moves them obscures the light of intellectual contemplation (57-68). The *canzone* is so exclusively an exercise in "natural philosophy," so centered on biological necessity, that consciousness itself is wholly excluded from consideration. The ethical dimension of love consists in the challenge its blind urgency presents to reason. "Nobility" is a matter of self-control, and the precarious happiness that such love affords has no ideal dimension.

Guido's influence on Dante was profound. But the *Vita nuova*, an anthology of Dante's early poetry interspersed with a narrative combining commentary on his poetic development with the history of his devotion to Beatrice during her earthly life, reveals a growing realization that his own conception of poetry and love differ fundamentally from Guido's. Like Guido Dante accepted love as being, for better or worse, fundamental to the noble life, and his early lyrics express a sense like Guido's of the internally divisive power of desire. But as the *Vita nuova* unfolds there is a gradual shift of focus: having failed to win his lady's favor by dramatizing his own sufferings, Dante resolves to devote his poetry henceforth wholly to praise of her [VN, c. 18.4-6]. The result of this new resolve is a *canzone*, "*Donne ch'avete intelletto d'amore*" ("Ladies who have intelligence of love"), which returns to the source of his inspiration and Guido's in the poetry of Guinizelli, and makes a wholly new departure. For Guido, the "heavenly" allure of the lady is a deception perpetrated by the senses, all the more dangerous as the lover's *gentilezza* responds more fully to the attraction of her beauty and subjects itself to the "fierce accident" of passion. Dante, too, sees that the experience his early, tormented lyrics depict is "an accident occurring in a substance" [VN 25.1-2], but the "fiery spirits of love" which strike the eyes of those on whom his lady bestows her greeting are not just goads to desire:

> *E quando trova alcun che degno sia*
> *di veder lei. quei prova sua vertute,*
> *ché li avvien, ciò che li dona, in salute,*
> *e sì l'umilia ch'ogni offesa oblia.*
> *Ancor l'ha Dio per maggior grazia dato*
> *che non pò mal finir chi l'ha parlato.*
>
> [*Donne ch'avete intelletto d'amore*, 37-42, VN 19.10]
>
> Translation:
> And when she finds one who is worthy to behold her, he feels her power, for what she bestows on him is restorative, and humbles him, so that he forgets any injury. Moreover God has made the power of her grace even greater, for no one who has spoken with her can

come to a bad end.

Pursuit of the lady's favor has become a test, not just of nobility, but of virtue. Her beauty is perfect, the fullest possible exampling of nature's power to reveal God's creative love. The climax of the *Vita nuova* occurs when Dante encounters Guido's lady, Giovanna, followed by his own Beatrice, "one marvel," as he says, "following the other" [VN 24.8]. At once he realizes that Giovanna's beauty, like the prophecy of the biblical Giovanni, is a precursor, heralding the "true light" of Beatrice, just as Guido's poetry of earthly love is finally a foil to his own celebration of the transcendent love revealed to him in Beatrice.

3. Philosophical Training

The philosophical content of the *Vita nuova* is minimal, a skeletal version of contemporary faculty psychology and a few brief references to metaphysics. But while finding his orientation as a poet Dante was also engaged in the study of philosophy, and spent "some thirty months" frequenting "the schools of the religious orders and the disputations of the philosophers" [*Conv*. 2.12.7]. This period must have included study in the Dominican school at Santa Maria Novella, where Dante could have learned logic and natural philosophy, and heard Fra Remigio de' Girolami (d. 1319) expound a theology based on Thomas and Aristotle [Panella; Davis (1984), 198-223]. Remigio, like Dante, read widely in classical literature of all sorts, and he was fond of drawing lessons in political and ethical conduct from his reading. For both Remigio and Dante, moreover, Thomas was primarily the author of the *Summa contra Gentiles* and the commentary on the *Ethics*, concerned, like Aristotle himself, to demonstrate the capacities of human reason as a means to truth.

Dante cites a dozen works of Aristotle, apparently at first hand, and shows a particularly intimate knowledge of the *Ethics*, largely derived, no doubt, from Thomas [Minio-Paluello]. But his Aristotelianism was nourished by other sources as well. Bruno Nardi has argued persuasively that his attitude toward the study of philosophy also owes a great deal to the more eclectic Albert the Great [Nardi (1967), 63-72; (1992), 28-29]. In Albert he encountered a wide-ranging encyclopedism which included original work, experimental and theoretical, in natural science, and treated Aristotelian natural philosophy and psychology in the light of a neo-Platonism derived from Arabic philosophers and such Greco-Arab sources as the *Liber de Causis*, as well as the Christian neo-Platonist tradition of the Pseudo-Dionysius. Albert aimed to discover Aristotle's own meaning, with the help of Greek and Arab commentators who led him into disagreement with other *Latini*, including at certain points his pupil Thomas, and he asserts more than once that philosophy and theology are separate spheres of knowledge. It was doubtless this willingness to pursue philosophy on its own terms that appealled to Dante, who also sought to distinguish philosophical and religious knowledge without simply subordinating the former to the latter.

Albert's view of the procession of the universe from the "substantial light" of the divine intellect through the operation of a hierarchy of lesser intelligences is clearly perceptible in Dante's treatment of the cosmic *intelligenze* or *sostanze separate* in the *Convivio* [*Conv*. 2.4-5; Nardi (1992), 47-62]. It shows up again in his treatment of the growth of the human embryo, which seems to imply, not a sequence of animations by nutritive, sensitive and intellective powers, as for Thomas, but the continuous operation of a single *virtus*

formativa, whose operation Albert compares to that of the *prima intelligentia* in the soul [*De intellectu & intelligibili* 2.2], and which is responsible not only for the development of the human creature but for effecting its union with an essentially external *anima intellectiva* [Boyde 270-79; Nardi (1960), 9-68; (1967), 67-70].

Albert is thus a likely conduit for seemingly Averroist elements in Dante's thought. He regards intellectual activity as the operation of the *intellectus agens*, through which the human soul is illumined by the divine Intelligence. Each soul possesses its own intellect, but this intellect is a "reflection" (*resultatio*) of the light of the primal mind, which thus, in effect, becomes itself the true agent intellect. Albert explicitly rejects the Averroist view of the active intellect as itself a celestial intelligence, a single, separate substance which actualizes in the passive intellect phantasms supplied by individual human minds. But he argues that only an intellect universal in nature can produce an understanding of universal forms. The intellect and the soul of which it is a function thus partake of the character of the separate intelligences. Soul is not the actualizing essence of the human creature, as in Thomas, but is related to body through the mediation of its organic faculties. In itself, through its agent intellect, the soul is drawn to contemplate the intelligences which order the universe at large, is informed by them with the transcendent knowledge they manifest, and finally "stands" in the divine intellect. In this way certain men are enabled to fulfil the innate human desire for understanding and attain a natural beatitude, "substantiated and formed in the divine being" [Albert, *De intellectu & intelligibili* 2.2-12; Nardi (1960), 145-50].

That this fulfillment is attained through natural understanding, with no recourse to the theology of grace and revelation, marks a crucial difference between Albert and Thomas, who devotes several chapters of the *Summa contra gentiles* to a forceful refutation of the notion that final happiness as defined by Aristotle is possible in this life [SCG 3.37-48]. For Thomas the desire to know is one and the same at all levels, and philosophy, seeking the causes of things, is ultimately "ordered entirely to the knowing of God" [SCG 3.25.9] Dante's own position on this question is difficult to define precisely. The poet of the *Paradiso* is at one with Thomas on the value of philosophy as consisting finally in its power to prepare the mind for faith [*Par*. 4.118-32; 29.13-45], but he shares Albert's fascination with natural understanding, and in earlier writings his willingness to grant philosophy a "beatitude" of its own hints at a latent dualism in his thought [Foster (1965), 51-71; (1977), 193-208].

Dante was surely aware also of a "radical" Aristotelianism centered in Bologna, where masters influenced by Siger of Brabant and Boethius of Dacia were affirming the autonomy of human reason and its capacity to attain happiness though its own powers [Corti (1981), 9-31; Vanni Rovighi]. But these thinkers, too, were following paths first taken by Albert, and his influence, together with that of Thomas, is sufficient to account for the distinctive features of Dante's use of philosophy. Whatever the precise channels, Dante was unquestionably one of the most learned Italian laymen of his day, aware of the issues contested in the schools, and at home with the modes of discourse in which they were discussed.

But there is also an old-fashioned strain in Dante's thinking, an idealistic, Platonizing view of the mental universe which recalls not just the neo-Platonized Aristotle of the *Liber de causis*, but the more primitive encyclopedism of twelfth- century thinkers like Bernardus Silvestris and Alan of Lille, poet-philosophers whose world view, inherited from late-antique neo-Platonism, was defined by the Liberal Arts and the

cosmology of Plato's *Timaeus* [Vasoli, 83-102; Garin, 64-70]. In Bernardus' *Cosmographia* and Alan's *Anticlaudianus*, the unfolding of the secrets of nature by the enquiring mind generates an allegory of intellectual pilgrimage toward truth. Dante's experience of philosophy, though defined in more dynamic and sophisticated terms, is a version of the same journey. The experience of love becomes a means to self-realization, and an awareness of the hierarchy of forces operative in the universe at large, which makes possible an *ascensus mentis ad sapientiam*, to that "amoroso uso della sapienza" which enables the human mind to participate in the divine.

4. The *Convivio*

The record of Dante's thirty months of study, and the fullest expression of his philosophical thought, is the *Convivio*, in which commentary on a series of his own *canzoni* is the occasion for the expression of a range of ideas on ethics, politics, and metaphysics, as well as for extended discussion of philosophy itself. Dante describes the genesis of his love of philosophy, and reflects on the ability of philosophical understanding to mediate religious truth, tracing the desire for knowledge from its origin as an inherent trait of human nature to the point at which the love of wisdom expresses itself directly as love of God.

Philosophy itself is the "love of Wisdom," and Dante's central metaphor for representing it is the poetic celebration of a noble lady, a *donna gentile*, an act which, like Guinizelli, he sees as involving the influence of cosmic powers. His poetry, "materiated" out of love and virtue [*Conv*. 1.1.14] comes into being because his nature is responsive to the influence of the "movers" of the universe, the intelligences, whose loving understanding determines "the most noble form of heaven" as they in turn respond to "the love of the Holy Spirit" [2.5.13, 18]. Their cosmic activity is a continual translation of understanding into love and natural process, and it is this which causes Dante to sing [2, Canzone, 1-9]:

> *Voi che 'ntendendo il terzo ciel movete,*
> *udite il ragionar ch'è nel mio core,*
> *ch'io nol so dire altrui, sì mi par novo.*
> *El ciel che segue lo vostro valore,*
> *gentili creature che voi sete,*
> *mi tragge ne lo stato ov'io mi trovo.*
> *Onde 'l parlar de la vita ch'io provo,*
> *par che si drizzi degnamente a vui:*
> *però vi priego che lo mi 'ntendiate.*
>
> Translation:
> You who by understanding move the third heaven, hear the discourse which is in my heart, and which seems so strange to me that I know not how to say it to others. The heaven which responds to your power, noble creatures that you are, draws me into the state in which I find myself, and so it seems that speech about the life I am experiencing is most appropriately addresses to you. Therefore I pray that you will understand me.

The intellective power or *intendimento* of the intelligences moves Dante to an utterance which only these same powers can fully understand. Thus there is a continuum, a process of *circulazione* which begins in the mind of God and descends through the work of the *intelligenze* to draw Dante's nature into that praise of the *donna gentile* which constitutes the fulfillment of his own nature, the highest expression of which his desire and intellect are capable [2.5.15, 18; 2.6.5].

Of the four books or *trattati* of the *Convivio* the first is largely a defense of Dante's decision to write his prose commentaries, as well as the poems they expound, in the Tuscan vernacular rather than in Latin. The second book provides a delineation of the Ptolemaic universe which the *intelligenze* govern, capped by a description of the Empyrean Heaven [2.3.8-11]:

> . . . outside all of these [spheres, heavens] the Catholics place the Empyrean heaven, which is to say, "the heaven of flame," or "luminous heaven"; and they hold it to be motionless because it has in itself, with respect to each of its parts, that which its matter desires. This is why the Primum Mobile has the swiftest movement; for because of the most fervent desire that each part of the ninth heaven has to be conjoined with every part of that divinest, tranquil heaven, to which it is contiguous, it revolves beneath it with such desire that its velocity is almost incomprehensible. Stillness and peace are the qualities of the place of that Supreme Deity which alone completely beholds itself. This is the place of the blessed spirits, according to the will of the Holy Church, which cannot lie. Aristotle, to anyone who rightly understands him, seems to hold the same opinion in the first book of *Heaven and the World* [i.e. *De caelo*]. This is the supreme edifice of the universe in which all the world is enclosed and beyond which there is nothing; it is not itself in space but was formed solely in the Primal Mind, which the Greeks call Protonoe. This is that magnificence of which the Psalmist spoke when he says to God: "Your magnificence is exaltled above the heavens."

The role of the Empyrean in thirteenth-century thought is equivocal. Some thinkers attempt to explain it scientifically, as a comprehensive cosmic principle, while for Thomas and Albert any such realm must be spiritual in nature, and can bear no natural relation to the astronomical universe, though both at times seem to grant it a certain influence on the natural order [Nardi (1967), 196-214; Vasoli, 94-102]. Dante's account reflects these uncertainties. He begins by citing "the Catholics," or orthodox belief, as authority for his account of this "abode of the supreme deity," but then goes on to treat the Empyrean as a created thing, "formed in the Primal Mind," and as the motionless cause of motion in the physical universe. If God dwells in this place, the Empyrean resides equally in Him, and the universe at large is encompassed, causally and locally, by the Empyrean. Dante deploys the Aristotelian physics of desire to explain the relationship of the Empyrean to the lesser heavens, yet it is at the same time beyond space, a wholly spiritual realm where blessed spirits participate in the divine mind. Dante seems to emphasize this double status by mingling theological and philosophical language, and invoking Aristotle and the neo-Platonists side by side with the poet of the Psalms. In the *Paradiso* the problems raised here will be implicitly resolved by a brilliant recourse to the "metaphysics of light"; when Dante and Beatrice, emerging from the "greatest body," the crystalline sphere or Primum Mobile, pass on "*al ciel ch'è pura luce, / Luce intellettual piena d'amore*" [*Par*. 30.39-40], we know that we are at the precise point at which the *bonum diffusivum sui* that is God's love transforms itself to cosmic energy, "the love that moves the sun and the

other stars." But poetry is perhaps the only means of defining this threshold [Bonaventure, *Sent*. 2. d. 2, a. 2, q. 1, c. 4; Thomas, *Quodl*. 6, q. 11, a. unicus 19].

Similar ambiguities appear in Dante's discussion of the *intelligenze* themselves. Since in governing the several heavens the intelligences engage in a kind of civil life, they must enjoy an active as well as a contemplative existence. But the latter is of a higher order than the former, and no single intelligence can partake of both. Influenced perhaps by Thomas's commentary, Dante imputes to Aristotle in the *Ethics* the view that such divine beings must know only a contemplative life [2.4.13; cp. Aristotle, NE 10.8, 1178b; Thomas, *Exp. Eth.* 10, lect. 12, 2125]. Dante's attempt to resolve the issue is oddly unpersuasive. He argues that the circular motion of the heavens, by which the world is governed, is really a function of the contemplative activity of the intelligences [2.4.13]. Here, as in the case of the Empyrean which they inhabit, we can see Aristotle's celestial movers undergoing a neo-Platonizing transformation, but Dante ends this stage of his discussion by noting that the truth concerning the Intelligences can not be fully grasped by our earthly understanding [2.4.16-17].

The second book concludes with an extended allegory in which the concentric "heavens" or planetary spheres are identified with the seven Liberal Arts, the "starry sphere" with physics and metaphysics, the *Primum mobile* with moral philosophy, and the Empyrean beyond with theology. This synthesis of the natural and the intellectual universe expresses an ideal of education which harks back to the late-antique sources of twelfth-century Platonism, but which Dante has imbued with new life. His emphasis on the ordering function of moral wisdom, and on the happiness attainable through intellectual contemplation, reflects an engagement with the philosophical tradition, and a commitment to philosophy as such, which belong to the later thirteenth century. The final chapter of Book Two affirms the beauty that consists in seeing the causes of those "wonders" which, as the opening of the *Metaphysics* declares, draw us to philosophy.

The third book is perhaps the most important for the student of Dante's knowledge and use of philosophy. Its central theme is praise of philosophy's power, as "l'amoroso uso della sapienza," "the loving use of wisdom," to impart the highest happiness to those who love her, perfecting their natures and drawing them close to God, of whose majesty and wisdom her beauty is the expression. It is largely a meditation on love, understood as Dante's response, intellectual, poetic and psychological, to his enlightenment at the hands of the beautiful lady whom he celebrates as Philosophy.

Early in the third book Dante cites the *Liber de Causis*: Every "substantial form" proceeds from the first cause, God, and participates in His divine nature according to its nobility [3.2.4-7; LC 1.1]. The human soul, noblest of all created forms, loves all things to the degree that they manifest the divine goodness, but desires above all to be united with God. Philosophy is the expression of this desire: Its "form" is "an almost divine love of knowledge" [3.11.13] which leads to "the spiritual uniting of the soul with what it loves" [3.2.3]. It is through philosophy that humanity perfects its "truly human or, better, angelic nature, that is to say the rational [nature]" [3.3.11], discovering in itself "that distinguished and most precious part which is deity" and "participating in the divine nature as an everlasting intelligence" [3.2.14, 19]. As such it mirrors the nobility, wisdom and love of the divine essence and its "loving use of wisdom" becomes by participation "marriage" with God [3.12.11-14].

All of this may appear sheer fantasy, but we should remember that the aim of philosophy as the *Convivio* pursues it is to attain, through natural reason, the greatest happiness of which we are capable in our earthly state. Such felicity is of course circumscribed by our mortality, and the Dante who can celebrate philosophical understanding as a quasi-mystical union with God knows at the same time that true union is granted only through grace, to a soul made receptive by the infusion of virtues which wholly transcend the workings of rational, natural virtue. For as Thomas says, the rational virtues "are dispositions by which man is fittingly disposed with reference to the nature by which he is a man. But the infused virtues dispose man in a higher way, and in view of a higher end; and also, it follows, with reference to some higher nature" [ST 1.2.110.3r]. This "higher nature" is of course the divine nature "through participation in which we are reborn in grace."

Dante acknowledges Thomas's distinction when he speaks of the soul after death as "more than human" [2.8.6], and asserts that to perceive God is not possible for our nature [3.15.10]. For both Dante and Thomas humanness is defined by the conjoining of soul and body, and human knowledge depends on the evidence of the senses [Foster (1965), 69-71; Thomas, ST 1.89a1]. Aristotle had similarly argued that a life of pure contemplation is beyond our strictly human capacity; we can live in this way only to the extent that we have in us "something divine" [NE 10.7, 1177b]. Thomas argues more subtly that the *modus essendi* of the soul joined to the body differs from that of the soul in separation; though they are the same in nature, the separated soul understands, not by means of sensory images, but "through species which it participates in by virtue of the divine light" [ST 1.89.1r]. In the meantime, as Dante acknowledges, there are truths which we can apprehend only as if in a dream, "*come sognando*," [*Conv*. 3.15.6; Nardi (1944), 81-90], and our desire for perfect understanding is necessarily limited, "proportionate to the wisdom which can be acquired here"; for to desire what is beyond the capacity of our intellectual nature would be ethically and rationally incoherent, a desire for imperfection rather than perfection of understanding [3.15.8-10].

But the *Convivio* continually strains against these limits. For Dante, first and foremost a poet of love, the experience of acquiring philosophical understanding has an important psychological component. By enabling us to analyze the processes of perception, philosophy brings us into contact with the true nature of things, and for Dante, as Kenelm Foster observes, the slightest such contact could have a metaphysical value [Foster (1965), 59-60]: "It did not in one sense matter to Dante what the particular object of his knowing might be, since the joy of knowing it was already a foretaste of all conceivable knowledge and all joy; and this precisely because, in knowing, the mind seized truth. . . . once intelligence, the truth-faculty, had tasted truth as such, that is, its own correspondence with reality, it could not help desiring truth whole and entire, that is, its correspondence with all reality." At this point knowledge and the joy of possessing it combine to prepare the ground for faith. By explaining phenomena which without her guidance would merely astonish us, philosophy inspires us to believe "that every miracle can be perceived by a superior intellect to have a reasonable cause" [3.14.14]:

> Our good faith has its origin in this, from which comes the hope that longs for things foreseen; and from this springs the activity of charity. By these three virtues we ascend to philosophize in that celestial Athens where Stoics and Peripatetics and Epicureans, by the

light of eternal truth, join ranks in a single harmonious will.

Philosophy thus conceived can still be regarded as the handmaid of theology, but as Dante develops his philosophical ideal metaphorically in terms of the beauty of the Donna Gentile, it assumes a religious value of its own. Since the wisdom she embodies is the consummation of human self-realization, the Donna Gentile resides in the divine mind as "the intentional exemplar of the human essence" [3.6.6]. In desiring her we desire our own perfection, for she is "as supremely perfect as the human essence can be." When at this point Dante adds a reminder that nothing in our human experience can fully satisfy this desire, he seems to be acknowledging that what Thomas' *Ethics* commentary calls "the ultimate end of desire's natural inclination" is unattainable in this life, since it would require an understanding more complete than any human being can possess [Thomas, *Exp. Eth*. 1, lect. 9, 107; SCG 3.48.2].

But having provided this caution, Dante seems to ignore it, as if unable to resist the conviction that philosophy satisfies our desire in a manner proper to itself. Everything naturally desires its own perfection, and for human beings this is "the perfection of reason" [3.15.3-4; cp. Thomas, *Exp. Eth*. 9, lect. 9, 1872]. But philosophy, as embodied in the Donna Gentile, is not just the consummation of natural understanding. For Dante, as for Aristotle, the human intellect as such is somehow more than human, and he is at times similarly unclear on the question of whether human beings can attain happiness through the exercise of virtue, and to what extent it is a gift of the gods [Foster (1977), 198-201]. Repeatedly he draws a distinction between merely human happiness and that attainable through grace, only to seemingly disregard it in subsequent discussion. Thus in the final chapter of the third treatise he acknowledges the "strong misgivings" that one might have about the happiness attainable through philosophy. Since certain things -- God, eternity, and primal matter are named -- exceed the capacity of our intellect, our natural desire to know must remain unfulfilled in this life [3.15.7]. Dante answers this by affirming, as noted above, that the natural desire for perfection is always proportionate to our capacity to attain it; for to desire the unattainable would be to desire our imperfection [3.15.8-11]. Human happiness, then, consists in the attainment of Aristotle's "human good," through the exercise of the virtues. This is what Dante calls "*l'umana operazione*," and its end is the highest that human beings can attain through their own powers.

Yet philosophy offers the promise of more. The same chapter is climaxed by the vision of Wisdom as "the mother of all things," the origin of all motion and order in the created universe, guiding the quest of human wisdom by the light of the divine intellect. When the human mind is fully informed by philosophy, it would appear, it becomes virtually one of the *intelligenze*, who know both what is above them and what is below, God as cause and the created universe as effect [3.6.4-6]. Thus Dante can speak of our rational nature as our "truly human, or, to speak more exactly, our angelic nature" [3.3.11], as if it enjoyed a more or less mystical existence of a higher order as well as that of the "merely" human nature that pursues the active life of virtue.

The *Liber de causis* says that each cause infuses into its effect the goodness it receives from its own cause, or, in the case of the soul, from God [*Conv*. 3.6.11; LC 4.48]. When in gazing on the body of the Donna Gentile we behold *maravigliose cose*, we are perceiving the effect of a cause which is ultimately God, and thus, Dante asserts [3.6.12-13]:

> it is evident that her form (that is, her soul), which directs the body as its proper cause, miraculously receives the goodness of God's grace. Thus outward appearance provides proof that this lady has been endowed and ennobled by God beyond what is due to our nature . . .

Thus in effect the Donna Gentile is the perfection we desire. Through her we experience the divine goodness, by an outflowing, a *discorrimento* which Dante glosses with a further reference to the *Liber de Causis* [3.7.2; LC 20.157], in terms of the hierarchical emanation of the divine goodness. In the quasi-continuous series of gradations that descends from angel to brute animal, there is no intervening grade between man and angel, so that some human beings are so noble as to be nothing less than angels [Aristotle, NE 7.1, 1145a]. Such is the Donna Gentile; she receives divine virtue just as the angels do [3.7.7]. She is a thing *visibilmente miraculosa*, ordained from eternity by God in *testimonio de la fede* for us [3.7.16-17; Foster (1965), 56]. Philosophy has "wisdom for her subject matter and love for her form" [3.14.1], and God, by instilling his radiance in her, "reduces" that love as nearly as possible to his own similitude [3.14.3; cp. Thomas, SCG 1.91].

Philosophy has clearly become far more than the means whereby human nature achieves self-realization, though this ideal continues to provide a framework for Dante's praise of her. She has assumed the status of Wisdom, *sapientia*, the divine mind as expressed in the order and harmony of creation. Her beauty can only be described in terms of its effects, like the separate substances and God Himself. The true philosopher "loves every part of wisdom, and wisdom every part of the philosopher, since she draws him to herself in full measure" [3.11.12]. Here we may recall Dante's account of how the swift motion of the Primum Mobile expresses its desire for total participation in the divinity of the Empyrean [2.3.8]. And it is in such terms that Dante ends his account of philosophy-as-wisdom. In the final chapter of the third treatise she is explicitly identified with the all-creating Wisdom of God [3.15.15], and Dante concludes in prophetic exhortation [3.15.17]:

> O worse than dead are you who flee her friendship! Open your eyes, and gaze forth! For she loved you before you existed, preparing and ordering your coming; and after you were made, she came to you in your own likeness in order to place you on the straight way.

The fourth treatise of the *Convivio* seems to have been written later than the first three, and it is markedly different in orientation. The principal theme of its *canzone* is the true nature of nobility. Introducing his prose discussion, Dante gives a curious account of how an interruption in his philosophical studies, caused by what the *canzone* calls "disdainful and harsh" behavior on the part of the Donna Gentile, provided an occasion for taking up this topic [4.1.8]:

> Since this lady of mine had somewhat altered the tenderness of her looks at me, especially in those features at which I would gaze when seeking to learn *whether the primal matter of the elements was intended by God* -- and for this reason I refrained for a short period of time from coming into the presence of her countenance -- while living, as it were, in her absence, I set about contemplating the shortcoming within man regarding the above-mentioned error [i.e. a false perception of the bases of human nobility].

That God is the creator of prime matter was an article of faith, and Thomas had dealt decisively with the role of divine will and intellect in the creative act [SCG 2.20.7, 21-24]. That Dante should admit to having entertained doubts about such a question is perhaps a way of indicating his awareness of a danger inherent in his philosophical studies. Deeply concerned to affirm the dignity of reason and the truth embodied in material creation, he may have sensed himself idolizing the secondary powers in whose hierarchical *circulazione* he felt himself, as poet, to be in a special sense participant, and allowing these preoccupations to cloud his awareness of God's omnipotence. The anger of the Donna Gentile would then express his sense of a corresponding loss of focus, a failure to affirm her unique and transcendent role in the expression of the divine will.

Whatever the precise nature of the dilemma to which Dante alludes, the fourth treatise is marked by a noticeable shift away from metaphysics in the direction of ethics and rhetoric. Philosophical knowledge is redirected to the purposes of social and political life, and the treatise, while punctuated like the others by numerous digressions, pursues a single sustained argument. Dante begins by explaining that social order as a condition of human happiness, and that it requires a single governor whose authority embraces that of all particular governors and directs their several efforts to a single end [4.4]. After a long digression on the role of Rome in the providential design of human history, he turns from political to philosophical authority, citing Aristotle as in effect the governor of the mind, "master and leader of human reason insofar as it is directed to man's highest work" [4.6.8]. He then proceeds to qualify both political and philosophical authority, justifying himself at length as he does so. Imputing to Aristotle the statement that "whatever appears true to the majority cannot be entirely false" [*Topica* 1.1, 100b? NE 1.9. 1098b?], he explains that this must be understood to apply, not to sense perception, but only to acts of the mind [4.8.6]. An emperor's authority, too, must be circumscribed; the art of ruling and the laws it creates cannot overrule rational judgment based on the laws of nature [4.9].

On this basis Dante proceeds to refute the view that nobility consists in wealth and ancestry, a view which he here attributes to Frederick II, "the last emperor of the Romans," and for which he will elsewhere cite Aristotle's *Politics* [*Mon*. 2.3.4; Pol. 4.8, 1294a]. Perhaps as significant as the arguments he musters to show the treacherous nature of riches and the uncertain course of nobility from one generation to another is the assertion of Dante's own authority, as philosopher and citizen, that is implied by his elaborate apology for speaking as he does [Ascoli, 35-41]. The gesture nicely epitomizes the project of the *Convivio*, a vernacular discourse which defines for its lay audience the limits of political and scholastic authority, and affirms the autonomy and potential dignity of individual human reason.

The later portions of the fourth treatise are grounded in another Aristotelian definition of nobility, as the perfection of a thing according to its nature [*Conv*. 4.16.7; *Physics* 7.3.246a]. The human expression of this perfection is virtue, moral and intellectual. Electing to address the moral virtues, as more accessible to a lay understanding, Dante begins by describing how nobility is implanted in the nascent soul as the seed of virtue, from which spring the two branches of the active and the contemplative life. The final chapters of the *Convivio* show how the virtues that stem from nobility can direct "the natural appetite of the mind," enabling it to evolve through love of them to the happiness which is the end of virtue [*Conv*. 4.17.8-9; NE 1.13, 1102a].

In the final stanza of the canzone analyzed in the fourth treatise, Dante addresses the poem itself as "Contra-li-erranti mia," "my song against-the-erring ones," and the final chapter of the commentary explains this as an allusion to the *Summa contra gentiles* of Thomas, written "to confound all those who stray from our faith" [*Conv*. 4.30.3]. By thus declaring himself the follower of so fine a craftsman, Dante suggests, he hopes to "ennoble" his own undertaking.

The *Contra gentiles* may seem an odd choice of model. Bruno Nardi considers that Dante had at most a superficial knowledge of this work at the time when he wrote the *Convivio*, and it is certainly the case that he is fundamentally at odds with Thomas over such specific matters as the origin of the soul, the role of the celestial intelligences in creation, and, more important, in claiming for philosophy the power to fulfil the human desire for knowledge in this life [Nardi (1992), 28-29]. On all of these matters Dante is closer to the position of Albert.

On the broader question of the nature of the human desire for knowledge, and the extent to which this desire can be fulfilled by the rational intellect, Dante remains, throughout the *Convivio*, sharply at odds with Thomas. The fourth treatise offers what we may take as his final word, as philosopher, on this question. Having dwelt at length on the insatiability of the base desire for riches, Dante addresses the question of whether our desire for knowledge, too, since it continues to grow as knowledge is acquired, is not similarly base. Dante begins his answer by asserting that "the supreme desire of each thing, and the one that is first given to it by nature, is to return to its first cause," and illustrates this proposition by the images of a traveller on an unfamiliar road, who imagines each house he encounters to be the inn he seeks, and the desires of youth, which focus first on an apple or a pet bird, then evolve to encompass love and prosperity [*Conv*. 4.12.15-16]. But while this may seem to evoke Thomas's view of a single desire which seeks to grow continuously toward union with God, Dante's point is that the path to fulfillment involves multiple desires and the attainment of multiple perfections [*Conv*. 34.13.2]:

> For if I desire to know the principles of natural things, as soon as I know them this desire is fulfilled and brought to an end. If I then desire to know what each of these principles is and how each exists, this is a new and separate desire. Nor by the appearance of this desire am I dispossessed of the perfection to which I was brought by the other, and this growth is not the cause of imperfection but of greater perfection.

Thomas can speak of the natural desire to know as a force like gravity, whose attraction intensifies as it approaches its object [SCG 3.25.13]. In contrast Dante's insistence on types and stages of knowing may seem almost perverse, a matter of emphasizing the stages of the mind's ascent rather than the desire that leads it forward from stage to stage. But what is at stake for Dante is the need to acknowledge human ends as having a definite value of their own, and this need will play an equally important role in Dante's other major philosophical work, the *Monarchia*.

Before leaving the *Convivio*, however, I would like to suggest a way in which Dante's citation of the *Summa contra gentiles* is, after all, an appropriate way of labelling his own undertaking. The *Contra gentiles* is unique among medieval *summae* in aiming to demonstrate, not just the compatibility of

Aristotelian physics and metaphysics with revealed truth, but the extent to which the *invisibilia Dei* can be understood without recourse to that truth. In Norman Kretzmann's phrase it is "a risky *tour de force*" that actively engages unbelievers in metaphysical argument, and spends more time undoing mistakes than affirming Christian doctrine. Revealed truth provides a means of determining the topics to be discussed, and the harmony of natural demonstration with revelation is repeatedly noted, but the basis for demonstration is provided by Aristotle, and what the first three of Thomas's four books present is a case, not for Christianity, but for theism [Kretzmann, pp. 43-53].

Dante seems to acknowledge the pioneering aspect of Thomas's undertaking. Like Thomas, he is testing philosophy, privileging Aristotle as a unique resource capable of helping him discover truth by natural means. Gauthier sees Thomas "nel mezzo del cammin" as he composes the *Contra gentiles*, adopting the position of the Aristotelian *sapiens* to reflect on his own ongoing work and justify it to contemporaries [Gauthier, 179-81]. Dante, too, is deeply concerned to define and justify his own position as a voice of wisdom for his contemporaries. The truths he affirms are encoded in his own poetry, rather than mysteriously embodied in Scripture, and he addresses a cultured but non-Latinate audience unschooled in philosophy. But in substituting the Donna Gentile of philosophical wisdom for Beatrice beata, the "authentic," salvific Beatrice who will reemerge as the voice of truth in the *Commedia*, Dante is establishing a relationship between secular knowledge and the truth that Beatrice embodies analogous to the relation Thomas establishes between philosophy and theology proper.

5. The *Monarchia*

The *Monarchia* is in its own way as idiosyncratic as the *Convivio*. Its purpose, foreshadowed in the discussion of empire in *Convivio* IV, is to demonstrate the necessity of a single ruling power, reverent toward but independent of the Church, capable of ordering the will of collective humanity in peace and concord. Under such a power the potential intellect of humanity can be fully actuated -- the intellect, that is, of collective humanity, existent throughout the world, acting as one. For just as a multitude of species must continually be generated to actualize the full potentiality of prime matter, so the full intellectual capacity of humanity cannot be realized at one time nor in a single individual [*Mon*. 1.3.3-8]. Here Dante adds his own further particularization of this Aristotelian doctrine [*De Anima* 3.5, 430a10-15], asserting that no single household, community, or city can bring it to realization. The ordering of the collective human will to the goal of realizing its intellectual potential requires universal peace [1.4], and this in turn requires a single ordering power through whose authority humanity may achieve unity and so realize the intention and likeness of God [1.8].

The basis of this argument for empire is evidently the first sentence of the Prologue to Thomas' literal commentary on the *Metaphysics*, where he declares that when several things are ordered to a single end, one of them must govern, "as the Philosopher teaches in his *Politics*" [Thomas, *Exp. Metaph.*, Proemium; Aristotle, *Politics* 1.5, 1254a-55a]. For Thomas this is only an analogy, a way of introducing the theme of order as it applies to the soul and its pursuit of happiness. The passage he cites from the *Politics* is concerned only with the rudiments of hierarchy; the idea of "ordering of things to one end" is present only by implication, and Aristotle makes no attempt to develop its metaphysical implications. Dante, however,

seems clearly to associate with Aristotle, or with Thomas' reference to Aristotle, the idea of "a political organization which leads in its way to 'beatitudo' for the whole human race" [Minio-Paluello, 74-77]. One may wonder if Dante's erroneous impression of the Aristotelian passage, which he cites directly with no reference to Thomas in both the *Convivio* and the *Monarchia* [*Conv*. 4.4.5; *Mon*. 1.5.3], is not a symptom of his intense need to draw the Philosopher into support of his view of world empire.

The second of the *Monarchia*'s three books deals with the great example of Rome, describing the city's providential role in world history, largely by way of citations from Roman literature aimed at demonstrating the consistent dedication of Roman power to the public good, and the conformity of Roman *imperium* with the order of nature and the will of God. The third book deals with the crucial issue of the relationship between political and ecclesiastical authority. Dante argues on various grounds that power in the temporal realm is neither derived from nor dependent on spiritual authority, though it benefits from the power of the Papacy to bless its activity. These arguments consist largely in refutations of traditional claims for the temporal authority of the Papacy, but the final chapter makes the argument on positive grounds. Since man consists of soul and body, his nature partakes of both the corruptible and the incorruptible. Uniting two natures, his existence must necessarily be ordered to the goals of both these natures [*Mon*. 3.16.7-9]:

> Ineffable providence has thus set before us two goals to aim at: i.e. happiness in this life, which consists in the exercise of our own powers and is figured in the earthly paradise; and happiness in the eternal life, which consists in the enjoyment of the vision of God (to which our own powers cannot raise us except with the help of God's light) and which is signified by the heavenly paradise. Now these two kinds of happiness must be reached by different means, as representing different ends. For we attain the first through the teachings of philosophy, provided that we follow them putting into practice the moral and intellectual virtues; whereas we attain the second through spiritual teachings which transcend human reason, provided that we follow them putting into practice the theological virtues, i.e. faith, hope, and charity. These ends and the means to attain them have been shown to us on the one hand by human reason, which has been entirely revealed to us by the philosophers, and on the other by the Holy Spirit . . .

This is Dante's most explicit, uncompromising claim for the autonomy of reason, reinforced by the entire world-historical argument of the *Monarchia* and constituting its final justification for world empire. Dante here goes well beyond Augustine's sense of the stabilizing function of empire, and eliminates any hint of the anti-Roman emphasis in Augustine's separation of the earthly and heavenly cities. In the final sentences of the *Monarchia* the temporal monarch becomes, like the aspiring intellect of the *Convivio*, the uniquely privileged beneficiary of a divine bounty which, "without any intermediary, descends into him from the Fountainhead of universal authority" [*Mon*. 3.16.15]. Like the Averroistic reasoning of his earlier claim that only under a world empire can humanity realize its intellectual destiny, this crowning claim shows Dante appropriating Aristotle to the service of a unique and almost desperate vision of empire as a redemptive force. But whether we consider the world view of the *Monarchia* an aberration [D'Entreves, 51] or take it as Dante's straightforward exposition of his views on the relations of secular and religious authority, its categorical definition of the twofold purpose of human life is impossible to

explain away. In the *Paradiso* [8.115-17] as in the *Monarchia*, to be a "citizen" is essential to human happiness, and the idea of an imperial authority independent of papal control remained fundamental to his political thought.

6. The *Commedia* (*The Divine Comedy*)

The *Monarchia*'s crowning vision is not Dante's last word on the subject of human happiness, nor on the possibility of achieving happiness by natural means. The "earthly paradise" which we attain for ourselves through philosophy is certainly not the paradise Dante the pilgrim will discover at the summit of Purgatory. To the philosopher the *Commedia* promises only the cold light and enamelled greenery of Limbo, the somber Elysium where Dante encounters Aristotle and the "philosophic family" who look to him as their master, living out an eternity, not of happiness, but of desire without hope [*Inf*. 4.111-20, 130-44].

The contrast expresses the difference in orientation between the *Commedia* on the one hand and the *Convivio* and *Monarchia* on the other. The *Commedia* is concerned always with the ultimate, eternal destiny of human life, with the transcendence, rather than the fulfillment of human understanding. When Beatrice at the summit of Purgatory utters prophetic words which "soar" far beyond Dante's power to envision her meaning, she explains that his limitations are those of "that school which you have followed," whose teachings are as far from the divine way as the earth from the *Primum Mobile* [*Purg*. 33.82-90]. The "school" in question is the study of philosophy as Dante had pursued and celebrated it in earlier writings. It is his training in this school that makes possible the luminous precision of the great doctrinal passages in the *Purgatorio* and *Paradiso* [*Purg*. 17.90-139; 25.37-87; *Par*. 2.112-48; 7.64-77; 13.52-78; 29.13-45; 30; 97-108], but it is a training that harbors the danger of rationalism and intellectual pride. In the *Convivio* God is the highest good, but remains the distant, unchanging focus of the aspiring mind. In the *Commedia* God assumes an active role as the dispenser of that grace without which the intellectual quest is futile:

> *Io veggio ben che già mai non si sazia*
> *nostro intelletto, se 'l ver non lo illustra*
> *di fuor dal qual nessun vero si spazia.*
>
> [*Par*. 4.124-26]
>
> Translation:
> I see well that never is our intellect satisfied, unless that truth illumines it beyond which no truth may soar.

Bibliography

Editions of Italian Texts

- Contini, Gianfranco, ed., *Poeti del duecento* (2 vols., Milan and Naples, 1960). Vol. II contains the poetry of Guido Guinizzelli and Guido Cavalcanti
- Dante, *Opere minori* (2 vols, Milan and Naples). Includes copiously annotated editions of the *Vita nuova* (Domenico de Robertis); *Convivio* (Cesare Vasoli); *Monarchia* (Bruno Nardi).
- Singleton, Charles, ed., *The Divine Comedy*, 6 volumes (Princeton, 1970-75). Clear prose facing-page translation, along with commentary volumes that quote generously from Thomas Aquinas and others.

Constitutionalism

Constitutionalism is the idea, often associated with the political theories of John Locke and the "founders" of the American republic, that government can and should be legally limited in its powers, and that its authority depends on its observing these limitations. This idea brings with it a host of vexing questions of interest not only to legal scholars, but to anyone keen to explore the legal and philosophical foundations of the state. How can a government be legally limited if law is the creation of government? Does this mean that a government can be "self-limiting," or is there some way of avoiding this implication? If meaningful limitation is to be possible, must constitutional constraints be somehow "entrenched"? Must they be enshrined in written rules? If so, how are they to be interpreted? In terms of literal meaning or the intentions of their authors, or in terms of the, possibly ever-changing, values they express? How one answers these questions depends crucially on how one conceives the nature, identity and authority of constitutions. Does a constitution establish a stable framework for the exercise of public power which is in some way fixed by factors like the original meaning or intentions? Or is it a "living tree" which grows and develops in tandem with changing political values and principles? These and other such questions are explored below.

1. Constitutionalism: a Minimal and a Rich Sense

In some minimal sense of the term, a "constitution" consists of a set of rules or norms creating, structuring and defining the limits of, government power or authority. Understood in this way, all states have constitutions and all states are constitutional states. Anything recognisable as a state must have some acknowledged means of constituting and specifying the limits (or lack thereof) placed upon the three basic forms of government power: legislative power (making new laws), executive power (implementing laws) and judicial power (adjudicating disputes under laws). Take the extreme case of an absolute monarch, Rex, who combines unlimited power in all three domains. If it is widely acknowledged that Rex has these powers, as well as the authority to exercise them at his pleasure, then the constitution of this state could be said to contain only one rule, which grants unlimited power to Rex. He is not *legally* answerable for the wisdom or morality of his decrees, nor is he bound by procedures, or any other kinds of limitations or requirements, in exercising his powers. Whatever he decrees is constitutionally valid.

When scholars talk of constitutionalism, however, they normally mean something that rules out Rex's case. They mean not only that there are rules creating legislative, executive and judicial powers, but that these rules impose limits on those powers.[1] Often these limitations are in the form of individual or group rights against government, rights to things like free expression, association, equality and due process of law. But constitutional limits come in a variety of forms. They can concern such things as the *scope* of authority (e.g. in a federal system, provincial or state governments may have authority over health care and education while the federal government's jurisdiction extends to national defence and transportation); the *mechanisms* used in exercising the relevant power (e.g. procedural requirements governing the form and manner of legislation); and of course *civil rights* (e.g. in a Charter or Bill of Rights). Constitutionalism in this richer sense of the term is the idea that government can/should be limited in its powers and that its authority depends on its observing these limitations. In this richer sense of the term, there is no "constitution" in Rex's society because the rules defining his authority impose no such limits. Compare a second state in which Regina has all the powers possessed by Rex except that she lacks authority to legislate on matters concerning religion. Suppose further that Regina also lacks authority to implement, or to adjudicate on the basis of, any law which exceeds the scope of her legislative competence. We have here the seeds of constitutionalism as that notion has come to be understood in Western legal thought.

In discussing the history and nature of constitutionalism, a comparison is often drawn between Thomas Hobbes and John Locke who are thought to have defended, respectively, the notion of a constitutionally unlimited sovereign (e.g. Rex) versus that of a sovereign limited by the terms of a social contract containing substantive limitations on her authority (e.g. Regina).[2] But an equally good focal point is the English legal theorist John Austin who, like Hobbes, thought that the very notion of limited sovereignty is incoherent. For Austin, all law is the command of a sovereign, and so the notion that the sovereign could be limited by law requires a sovereign who is self-binding, who commands him/her/itself. But no

one can "command" himself, except in some figurative sense, so the notion of limited sovereignty is, for Austin (and Hobbes), as incoherent as the idea of a square circle.[3] Though this feature of Austin's theory has some plausibility when applied to the British Parliamentary system, where Parliament is often said to be "supreme" and constitutionally unlimited,[4] it faces serious difficulty when applied to most other constitutional democracies such as one finds in the United States and Germany, where it is clear that the powers of government are legally limited by a constitution. Austin's answer was to say that sovereignty may lie with the people, or some other person or body whose authority is unlimited. *Government bodies* -- e.g. Parliament or the judiciary -- can be limited by constitutional law, but the sovereign -- i.e. "the people" -- remains unlimited. Whether this provides Austin with an adequate means of dealing with constitutional democracies is highly questionable. For Austin's sovereign is a determinate individual or group of individuals whose commands *to others* constitute law. But if we identify the commanders with "the people", then we have the paradoxical result identified by H.L.A. Hart -- the commanders are commanding the commanders. In short, we lapse into incoherence.[5]

2. Sovereign versus Government

Though there are serious difficulties inherent in Austin's attempt to make sense of "the people's sovereignty," his account does bring out the need to distinguish between two different concepts: sovereignty and government. Roughly speaking, we might define "sovereignty" as the possession of supreme (and possibly unlimited) power and authority over some domain, and "government" as those persons or bodies through whom sovereignty is exercised. Once some such distinction is drawn, we see immediately that sovereignty might lie somewhere other than with the government. And once this implication is accepted, we can coherently go on to speak of *limited* government coupled with *unlimited* sovereignty. Arguably this is what one should say about constitutional democracies where the people's sovereignty is thought to be unlimited but the government's power is constitutionally limited. As Locke held, unlimited sovereignty remains with the people who have the normative power to void the authority of their government (or some part thereof) if it exceeds its constitutional limitations.

Though sovereignty and government are different notions, it does seem possible for them to apply to the same individual or body. It is arguable that Hobbes insisted on the identification of sovereign and government insofar as he seemed to require a (virtually) complete transfer of all rights and powers from sovereign individuals to a political sovereign whose authority was to be absolute, thus rendering it possible to emerge from the wretched state of nature in which life is "solitary, poor, nasty, brutish and short."[6] In Hobbes' theory, supreme sovereignty must reside in the supreme governmental person or body who enjoys unlimited power and authority to rule the commonwealth. Anything less than unlimited government would, given human nature and the world we inhabit, destroy the very possibility of stable government. So even if "sovereignty" and "government" are different notions, this neither means nor implies that the two could not apply to one and the same individual(s).

3. Entrenchment

According to most theorists, a further important feature of constitutionalism is that the rules imposing limits upon government power must be in some way be *entrenched*, either by law or by way of "constitutional convention."[7] In other words, those whose powers are constitutionally limited -- i.e. the organs of government -- must not be legally entitled to change or expunge those limits at their pleasure. Most written constitutions contain amending formulae which can be triggered by, and require the participation of, the government bodies whose powers they limit. But these formulae invariably require something more than a simple decision on the part of the present government to invoke a change. Sometimes constitutional assemblies are required, or super-majority votes, referendums, or the agreement of not only the central government in a federal system but also some number or percentage of the governments or regional units within the federal system. Entrenchment not only facilitates a degree of stability over time (a characteristic aspiration of constitutional regimes), it is arguably a requirement of *the very possibility* of constitutionally limited government. Were a government entitled, at its pleasure, to change the very terms of its constitutional limitations, there would, in reality, be no such limitations.

Consider Regina once again. Were she entitled, at her discretion, to remove (and perhaps later reinstate) the constitutional restriction preventing her from legislating on religious matters, then it is questionable whether she could sensibly be said to be "bound" by this requirement. On the other hand, were there a constitutional rule or convention specifying that Regina is entitled to remove this restriction only if she succeeds in convincing two thirds of her subjects to vote for the change, then we might meaningfully speak of constitutional limitation. Of course this constitutional meta-rule or convention is itself subject to change or elimination -- a fact which raises a host of further puzzles. For example, does such an act require application of the very rule in question -- i.e. two third's majority vote -- or are "the people," as sovereign, at liberty to change or expunge it at *their* pleasure? If we accept the distinction between government and sovereignty urged above, as well as the proposition that sovereignty cannot be self-limiting, (X cannot limit X) then we seem led to the conclusion that the constitutional meta-rule -- and hence the constitutional regime of which it is an integral part -- both exist at the pleasure of the people. Entrenchment may be an essential element of constitutional regimes, but constitutions cannot be entrenched against the actions of "the sovereign people" at whose pleasure they exist.

4. "Writtenness"

Some scholars believe that constitutional rules do not exist unless they are in some way enshrined in a written document.[8] Others argue that constitutions can be unwritten, and cite, as an obvious example of this possibility, the constitution of the United Kingdom. One must be careful here, however. Though the UK has nothing resembling the American Constitution and its Bill of Rights, it nevertheless contains a number of written instruments which arguably form a central element of its constitution. Magna Carta (1215 A.D.) is perhaps the earliest document of the British constitution, while others include The Petition of Right (1628) and the Bill of Rights (1689). Furthermore, constitutional limits are also said to be found in certain principles of the common law, explicitly cited in landmark cases concerning the limits of government power. The fact remains, however, that Britain seems largely to have an unwritten constitution, suggesting strongly that writtenness is not a defining feature of constitutionalism.

Why would one think that constitutional norms must be written rules, as opposed to more informal conventions or social rules? One possible reason is that unwritten rules are sometimes less precise and therefore more open to "interpretation," gradual change, and ultimately avoidance, than written ones. If this were true, then an unwritten rule could not, as a practical matter, serve adequately to limit government power. But this need not be the case. Long standing social rules and conventions are often clear and precise, as well as more rigid and entrenched than written ones, if only because their elimination, alteration or re-interpretation typically requires widespread changes in traditional attitudes, beliefs and behaviour.

5. Montesquieu and the Separation of Powers

Does the idea of constitutionalism require, as a matter of conceptual or practical necessity, the division of powers urged by Montesquieu? In Regina's case, there is no such separation. But how, it might be asked, can she be the one (qua judge) who determines whether her legislation satisfies the prescribed constitutional limitation? Even if, *in theory*, Regina's constitution prohibits her from removing her constitutional restriction at will (because she must observe the 2/3rds meta-rule)she can always choose to ignore her restrictions, or to "interpret" them so as to escape their binding force. Perhaps Bishop Hoadly was right when he said (1717) in a sermon before the English King: "Whoever hath an ultimate authority to interpret any written or spoken laws, it is he who is truly the Law-giver to all intents and purposes, and not the person who first wrote or spoke them."[9] Although some constitutional limits, e.g. one which restricts the Mexican President to a single term of office, seldom raise questions of interpretation, many others are ripe for such questions. Regina might argue that a decree requiring all shops to close on Sundays (the common Sabbath) does not concern a religious matter because its aim is a common day of rest, not religious observance. Others might argue, with seemingly equal plausibility, that it does concern a religious matter and therefore lies outside Regina's legislative competence. That constitutions often raise such interpretive questions gives rise to an important question: Does the possibility of constitutional limitation on supreme legislative (and executive) power require, as a matter of practical politics, that judicial power reside in some individual or group of individuals distinct from that in which legislative and executive powers are vested? In modern terms, must constitutional limits on a legislative body like Parliament, the Duma or Congress, or an executive body like the President or her Cabinet, be subject to interpretation and enforcement by an independent judiciary?

Marbury v Madison settled this question in the affirmative as a matter of American law, and most nations follow *Marbury* (and Montesquieu) in accepting the practical necessity of some such arrangement. But it is not clear that the arrangement truly is practically necessary, let alone conceptually so. Bishop Hoadly notwithstanding, there is nothing nonsensical in the suggestion that X might be bound by an entrenched rule, *R*, whose interpretation and implementation is left to *X*. What *R* actually requires is not necessarily identical with what *X* thinks or says that it requires, any more than what the American Constitution requires is necessarily identical with what the American Supreme Court says that it requires. This is so even when there is no superior institution to correct *X*'s judgment, or that of the American Supreme Court, when they go wrong. That constitutional limits can sometimes be interpreted so as to avoid their effect, and no recourse be available to correct mistaken interpretations and abuses of power, does not,

then, imply the absence of constitutional limitation. But does it imply the absence of *effective* limitation? Perhaps so, but even here there is reason to be cautious in drawing general conclusions. There is a long-standing tradition within the British Parliamentary system according to which Parliament is alone in being able not only to create, but also to interpret and implement its own constitutional limits. And whatever its faults, there is little doubt that Parliament typically acts responsibly in observing its own constitutional limits.

6. Constitutional Law versus Constitutional Convention

The idea of constitutionalism is usually thought to require *legal* limitation on government power and authority. But according to most constitutional scholars, there is more to a constitution than constitutional law. Many people will find this suggestion puzzling, believing their constitution to be nothing more (and nothing less) than a formal document, possibly adopted at a special constitutional assembly, which contains the nation's supreme law. But there is a long-standing tradition of conceiving of constitutions as containing much more than constitutional law. Dicey is famous for proposing that, in addition to constitutional law, the British constitutional system contains a number of "constitutional conventions" which effectively limit government in the absence of legal limitation. These are, in effect, social rules arising within the practices of the *political* community and which impose important, but *non-legal*, limits on government powers. An example of a British constitutional convention is the rule that the Queen may not refuse Royal Assent to any bill passed by both Houses of the UK Parliament. Perhaps another example lies in a convention that individuals chosen to represent the State of Florida in the American Electoral College (the body which actually chooses the American President by majority vote) must vote for the Presidential candidate for whom a plurality of Floridians voted on election night. Owing to the fact that they are political conventions, unenforceable in courts of law, constitutional conventions are said to be distinguishable from constitutional laws, which can indeed be legally enforced. If we accept Dicey's distinction, we must not identify the constitution with constitutional law. It includes constitutional conventions as well. We must further recognize the possibility that a government, though *legally* within its power to embark upon a particular course of action, might nevertheless be *constitutionally* prohibited from doing so. It is possible that, as a matter of law, Regina might enjoy unlimited legislative, executive and judicial powers which are nonetheless limited by constitutional conventions specifying how those powers are to be exercised. Should she violate one of these conventions, she would be acting legally, but unconstitutionally, and her subjects might well feel warranted in removing her from office -- a puzzling result only if one thinks that all there is to a constitution is constitutional law.

7. Constitutional Interpretation and Constitutional Theories

As we have just seen, there is (often) more to a constitution than constitutional law. As we have also

seen, constitutional norms need not always be written rules. Despite these important observations, two facts must be acknowledged: (1) the vast majority of constitutional cases hinge on questions of constitutional law; and (2) modern constitutions are predominantly written documents.[11] Consequently, constitutional cases often raise theoretical issues concerning the proper approach to the interpretation of written instruments -- coloured, of course, by the special role of constitutions in defining and limiting the authority and powers of government.

8. The Fixed View and the Living Tree

Although theories of constitutional interpretation are many and varied, they all seem, in one way or another, to ascribe importance to a select number of key factors: textual meaning, political and legal history, intention, and moral/political theory. The roles played by these factors in a theory depend crucially on how the theorist conceives of a constitution and its role in limiting government power. For example, if a theorist views a constitution as foundational law whose existence, meaning and authority derive from the determinate, historical acts of its authors and/or those they represent(ed), and whose principal point is to *fix* a framework within which government power is to be exercised, she may be inclined towards an interpretative theory which accords pride of place to factors like authors' intentions, and literal or plain meaning insofar as the latter is considered the best guide to the former. On what we will call the "*fixed view*" of a constitution, it is natural to think that such factors should govern whenever these are clear and consistent. On the fixed view, a constitution sets a framework for law and politics which is fixed by the historical acts of its authors; it is therefore wholly inappropriate for a judge to ignore such factors when she interprets its provisions, even when doing so would allow her to avoid results which appear unacceptable, perhaps even unjust.

If, on the other hand, one views a constitution as a "*living tree*", which by its nature grows and adapts to contemporary circumstances and beliefs, and whose authority resides in its justice, or in the consent, commitment or sovereignty of "the people *now*," not "the people *then*," then one will be far less likely to find such appeals persuasive, let alone conclusive. One inclined towards the living tree conception will tend to spurn appeals to textual meaning and authors' intentions as attempts to impose the dead hand of the (possibly distant) past upon contemporary society and practice. Government must be limited in power, but the terms of these limitations should be allowed to evolve and adapt in light of changing circumstances and political beliefs. Despite its undoubted appeal to some, the living tree conception faces tough questions: is viewing a constitution as a "living tree", malleable in the hands of contemporary interpreters -- particularly judges -- consistent with its status as foundational law, and with the entrenchment, stability and protection from unwarranted state power which seem to be crucial, if not essential, aspects of the very idea of constitutionally limited government? Different theories of constitutional interpretation split on how they answer this important question.

9. Textualism: The Meaning of a Constitution's Text

No one denies that the literal meanings of the actual words chosen in drafting a constitution play a key

role in determining its impact upon decisions, just as they do in the interpretation of statutes, wills, consent forms, and any other written (and sometimes unwritten) legal instruments. Despite factors such as vagueness, open texture, indeterminacy and the like, the semantic content of a constitutional provision, as a rule or norm intended to convey meaning through the use of words, sets limits to its proper interpretation. As Alice said, words can't just mean whatever one wants them to mean.

Textualism appeals to many, but especially those who accept the fixed view of the constitution, coupled with a belief that a constitution is, principally, one important device through which citizens are protected from unwarranted state power, including unwarranted *judicial* power. Requiring that judges interpret constitutional provisions in light of the meaning of the constitution's text (particularly the "original meaning" it bore at the time of his adoption) respects the role of the founders in fixing, on behalf of the community, the basic framework of government and the limits within which state power is to be exercised. Political decisions about that proper framework and its constituent limits have, on this theory, already been made in a proper forum by those in whose hands such decisions were rightly placed. Their decisions have been communicated and should not, lest stability and legitimacy be threatened, be subject to continuous revisiting and review, particularly by (typically unelected) judges who lack the authority enjoyed by the constitution's authors. The discovery of textual meaning is (it is thought) a largely factual matter, requiring none of the moral and political reasoning appropriately undertaken by the founders. If constitutional change is required, the constitution itself sets procedures through which such changes can be affected. Should these prove ineffective, and yet change still be warranted, then the people, as the sovereign power underlying constitutional democracies, have the authority to abandon the constitution, through revolution, peaceful or not, and to substitute something else. But so long as the constitution remains in force, the semantic content of its rules must be taken as governing all matters of constitutional law.

Despite its obvious appeal, Textualism -- or as it is sometimes called, "strict constuctionism" -- faces a number of difficulties. First, semantic content is not always fully determinate or stable from one generation to the next. This is especially true of words and phrases like "equality," "due process of law," "fundamental justice," "free and democratic society," "freedom of religion" and so on. These seem to lack the determinate and relatively stable semantic content of phrases like "five year term" or "two-thirds majority." The evaluative concepts expressed by the former are highly contestable politically, perhaps even "essentially contestable," and cannot therefore serve the role suggested by the fixed view.

Textualism faces a further difficulty. Even when the meaning of a word or phrase used in a constitution is plain for all to see, it is not always the case that it is considered dispositive. For example, taken in terms of both its original and (perhaps different) contemporary meaning, the First Amendment of the American Constitution is clearly violated by a whole host of American laws, e.g., those proscribing incitement, perjury and libel. Taken literally the First Amendment renders unconstitutional *any law* which in *any way* restricts freedom of speech. If so, then it is unconstitutional in the United States to punish untruthful witnesses, prevent primary school teachers from uttering vicious racial slurs against their minority students, or convict those who incite crowds to violence. But such actions have never been understood to violate the First amendment, leading to the inevitable conclusion that more than semantic meaning governs its interpretation and application. And this is generally, if not universally, true of

modern states and their constitutions. But if more than meaning governs, what else counts? The most obvious choice, especially for those attracted to the fixed view, are the "intentions" of the framers. In response to the suggestion that the American First Amendment prohibits laws against perjury, a defender of the fixed view is likely to reply: "But that can't possibly be what the framers had in mind -- what they intended -- in choosing the words they did." This leads us to a second type of interpretive theory, Originalism, which focusses, not on word meaning, but on the *intentions* of those by whose actions the constitution's various provisions came into existence.

10. Originalism

An Originalist might claim that Textualism is partially correct but doesn't go far enough. The original intentions of a constitution's authors are what really count; and the reason that textual meaning is so important is that it's often the most reliable guide to those intentions. The drafters of a constitution may be presumed to have known and had in mind the standard applications of the words they used, and to have intended the results suggested by those applications, together with the goals and values those applications were best suited to achieve. But when textual meaning fails, direct appeal to the relevant intentions is necessary. In both kinds of cases, however, the ultimate aim is to respect original intentions.

Whatever its precise contours, an Originalist theory is, like Textualism, likely to rest on the fixed view of a constitution. To be sure, the constitution's rules are fixed by the authors' intentions in deciding as they did, and not by the semantic content of the words chosen to communicate those intentions. But they are fixed nonetheless, and must, as a result, not be revisited and revised lest the authority and stability of the constitution be threatened. The intentions of those by whose authority a constitution is made must always govern its interpretation, not the new value judgments and decisions of contemporary judges (or any other interpreters) asking the very same questions the founders intentions were supposed to have settled.

Originalism faces a number of difficulties, some shared with Textualism. For example, original intentions are often unclear, if not completely indeterminate, leaving the interpreter with the need to appeal to other factors. Original intentions can vary from one author to the next, and can range from the very general to the highly specific. At one end of the spectrum are the various, and sometimes conflicting *goals and values* the authors of a provision intended their creation to achieve. At the other end are the very specific *applications* the authors might have had in mind when they chose the provision they did. Did the intended applications of an equality provision encompass *equal access to the legal system* by all groups within society? Or only something more specific like equal access to *fairness at trial*? Did they perhaps include *equal economic and social opportunities* for all groups within society? Different authors might have "intended" all, none, or some of these applications when they chose the equality provision. And as with the general goals and values underlying a provision, there is room for inconsistency and conflict. Constitutional authors, no less than legislators, union activists, or the members of a church synod, can have different goals and applications in mind *and yet settle on the same set of words*. In light of this fact, it is often unhelpful to rely on original intentions when interpreting a constitution.

11. Hypothetical Intent Theory

One of the most serious difficulties faced by Originalism is that contemporary life is often very different from the life contemplated by the authors of a constitution. As a result, many intended applications may now seem absurd or highly undesirable in light of new scientific and social developments and improved moral understanding. Modern life includes countless situations which the authors of a constitution could not possibly have contemplated, let alone intended to be dealt with in any particular way. The right to free speech which found its way into many constitutions in the early modern period, could not possibly have been intended by its defenders to encompass, e.g., pornography on the internet. In response to such difficulties, an Originalist might appeal to what we can call "hypothetical intent." The basic idea is that we should always consider, in such instances, the hypothetical question of what the original authors *would have intended* to be done in the case at hand had they known what we now know to be true. We are, on this view, to put ourselves imaginatively in the authors' shoes, and determine, in light of their intended goals and values, and possibly by way of analogy with their intended applications, what they would have wanted to be done in the new circumstances.

The Hypothetical Intent Theory faces difficulties too. First, the theory presupposes that we can single out one, consistent set of values, goals and applications attributable to the authors, in terms of which we are to ask the question: What would they have wanted to have done given these (intended) values, goals and applications? But as we have already seen, the authors of a constitution invariably have different things in mind when they agree on a constitutional text. Second, even if we could single out, at some appropriate level of generality, a set of goals, values and applications from which our hypothetical inquiry is to proceed, it is unlikely that there will always be a uniquely correct answer to the question of what the authors would have intended in these cases which they did not anticipate and could not possibly have imagined. What would an 18th century founder, firmly in favour of freedom of speech, have thought about child pornography on the internet? Thirdly, and perhaps most importantly, we are left with the question of why it much matters what a long dead group of individuals might have wanted done were they apprised of what we now know. The main appeal of the original intent theory is that it appears to tie constitutional interpretation to *historical decisions actually made* by individuals with authority to decide questions concerning the proper limits of government power. If we are now to consider, not what they *did* decide, but what they *might have decided* had they known what we now know, then the question naturally arises: Why not just forget this theoretically suspect, hypothetical exercise and make the decisions ourselves? There is some plausibility in the claim that the decision should be made in light of the very general goals and values probably intended by the authors -- if, that is, one could discover what these were and if they could all be rendered consistent. But why should we wish to perpetuate their possibly misguided views about the appropriate ways in which to secure these goals and values? Unless we reject completely the idea that there might be moral progress, or the idea that any such progress must always be dismissed for the sake of a fixedness allegedly guaranteed by adherence to authors' intent, there seems little reason to believe that we should be so tied. To think otherwise might well be to allow the dead hand of the past to govern the affairs of today.

True enough, it might be replied. But the alternative is one which undermines the very point of

constitutions. If we view a constitution as a living tree whose limitations are constantly open to revisiting and revision in light of changing times and improved moral/political understanding, then it can no longer function as a stable instrument whose very point and purpose is to limit the power of government -- particularly, though not exclusively, arbitrary judicial power. Arguments of political morality may be necessary to frame a constitution, but if judges and other contemporary interpreters are allowed to construe it in light of how they choose to understand those limits, then the possibility of limitation vanishes. But does it? One theorist who thinks not is Ronald Dworkin, whose theory of constitutional interpretation attempts to do justice to both these points of view.

12. Dworkin: Moral Theory

For Dworkin, historical factors like semantic meaning and intention, though always important, are in no way dispositive. They in no way *fix* the limits of government until such time as an amendment passes or a revolution occurs. On the contrary, constitutions frame the terms of an ongoing political debate about the moral principles of justice, fairness and due process underlying a nation's constitutional limits on government power. And as the political community's understanding of these principles develops and improves, the very content of the constitution develops and, it is hoped, improves along with it.

A crucial element in Dworkin's constitutional theory is his general claim that the law of a community includes more than any explicit rules and decisions authoritatively adopted in accordance with accepted procedures. It does, of course, include many such rules and decisions and these can be found, paradigmatically, in statute books, judicial decisions and, of course, written constitutions. These are often termed "positive law." But the positive law in no way exhausts the law according to Dworkin. Most importantly, for our purposes, it in no way exhausts that part of law we call "the constitution." In Dworkin's view, a constitution includes the principles of political morality which provide the best explanation and moral justification -- i.e. the best interpretation -- of whatever limits have been expressed in positive law. Hence, constitutional interpretation must always invoke a theory of political morality. One concerned to interpret the limits upon government power and authority imposed by a constitution must look to an interpretive theory which provides the positive constitutional law with its morally best explanation and justification.

The development of an interpretive theory of the constitution is, Dworkin acknowledges, an extremely difficult task, and people of good will and integrity will reasonably disagree about which theory is best. There is no mechanical, morally neutral test to apply, only the competing interpretations of those whose task it is to interpret. This does not mean, however, that attempting to evaluate theories is foolish, or that there really is no such thing as a best theory since there is no mechanical way of discovering it. The presence of disagreement, controversy, and uncertainty in constitutional cases, does not entail that there are no right answers to the questions posed, and no uniquely correct theory which determines what those answers are and hence what the constitution actually requires. The presence of such factors entails only that interpreters must, as they must do in all interpretive enterprises, including the arts, the sciences, and the law, exercise judgment in fashioning their interpretive theories. Dworkin goes so far as to argue that in a mature legal system there almost always is a best constitutional theory, and judges (and legislators)

are duty-bound to try their best to discern and implement its requirements in making their decisions.

There are, for our purposes, three important implications of Dworkin's theory of constitutional interpretation. First, original intentions and semantic meaning at best set the stage for the debates in political morality which constitutional cases both require and licence. They seldom, if ever, settle matters. Second, constitutional cases require the kind of decision-making which is, on the Originalist and Textualist theories, properly undertaken only by those who have already fixed the standards contained within the constitution -- i.e. its authors or framers. The kind of morally neutral decision-making, under standards set by other responsible agents, to which the Originalist and Textualist theories aspire, is simply impossible on Dworkin's theory. Dworkin's theory requires wholesale rejection of the fixed view.The constitution is not a finished product handed down in a form fixed till such time as its amending formula is invoked successfully or a revolution occurs. Rather it is a work in progress requiring continual revisiting and reworking as our theories concerning its limits are refined and improved. It is, in short, a living tree.

A third, related implication of Dworkin's theory is that judges in constitutional cases are not merely agents of the authors in carrying out their explicit decisions. On the contrary, they are partners with the authors in an ongoing project, one which requires participants, both then and now, to engage in the kind of moral decision-making which, on the fixed view, settled matters when the constitution was adopted (and/or amended). The limits to government power are, on Dworkin's theory, essentially contestable, ad infinitum. If there is a correct theory of a constitution, it requires, for its development and elaboration, an interpreter of super-human powers of moral, political and legal reasoning. In short, it requires Dworkin's judge Hercules.[12] But Hercules is a product of Dworkin's imagination, and so the project of interpreting the contestable terms of constitutions is an ongoing one, requiring each and every interpreter to provide her own best, and undoubtedly imperfect, interpretation of the limits placed upon government by her constitution. The latter is never fixed.

13. Critical Theory

That it requires the skill, acumen and insight of a Hercules is seen by many theorists as a serious drawback of Dworkin's approach to constitutional interpretation. If ordinary judges, with their limited skill, integrity and objectivity are at liberty to decide in terms of their own, highly contestable moral theories of the constitution, then the inevitable result is a kind of unbridled judicial activism which threatens the stability and legitimacy of the constitution and the limits on government power which it is supposed to represent. Instead of limitations properly fixed and settled by apolitical factors like historical intentions and meanings, we would have "limitations" continually in flux and subject to different interpretations by different judges with their own theories of political morality. Those of an originalist or texualist bent will see in such consequences sufficient reason to reject Dworkin's theory in favour of their alternative. But for many constitutional scholars, originalism and textualism are as problematic as Dworkin's interpretive theory. For these "critical theorists", semantic meaning, historical intentions, and herculean interpretive theory, all fail, in one way or the other, to fix meaningful limits upon government power.[13] As a result, reliance on such factors in constitutional adjudication only serves to rationalize the

purely political decisions by judges pursuing, consciously or not, their own political ideologies. A further consequence is suppression of those -- women, minority racial groups, the poor, and so on -- whose interests are not supported by these ideologies. Instead of the curbing of arbitrary government power for which the idea of constitutionalism is supposed to stand, we have political suppression disguised in a cloak of false constitutional legitimacy.

So critical theorists are highly skeptical of constitutional practice and theories which applaud constitutionalism as a bulwark against oppression.[14] As we saw at the outset, a key element in the idea of constitutionalism is that government can/should be limited in its powers and that its authority depends on observance of those limits. We further noted that the authority of constitutions in liberal democracies is generally thought to lie in "the people." One important implication of critical theory is that the concept of " the people" is as much a fabrication as is Dworkin's Hercules. Instead of "we the people", western societies are comprised of various groups competing either for domination (e.g., white males and the wealthy) or for recognition and the elimination of oppression (e.g. the poor, women, and racial minorities). The law, including constitutional law, is a powerful tool which has, historically, been utilized by dominant groups to secure and maintain their superior status. As such, a constitution is anything but the protection from unwarranted power that its champions have heralded over the centuries. What is taken to be the plain meaning of the word "equality" is what the dominant group understands it to be. What is taken to be the obvious historical intentions of the framers is whatever intentions fit the ideologies of the dominant groups. What is taken to be the best moral theory underlying the constitution is nothing more than a rationalization of current social structures, all of which systematically oppress the interests of women, minorities and the poor.

Critical theories represent a serious challenge not only to conventional theories and established practices of constitutional interpretation, but to the very idea of constitutionalism itself -- the idea that government can and should be limited in ways which serve to protect us from unwarranted state power. According to originalists and textualists, the constitution protects us from judges and other officials by restricting them to morally neutral decisions about historical intentions and semantic meanings. According to Dworkin, it is Hercules' best moral theory of the constitution which serves as the bulwark against oppression. One crucial feature of Hercules' theory is that it is often at odds with received opinion, in particular with the self-serving convictions and prejudices of the various dominant groups within society. Following Hercules' moral theory of the constitution will lead a judge to protect the rights of oppressed groups from the power of dominant groups, especially when that power has the sanction of legislation. But the ordinary judge is not, critical theorists will insist, identical with Hercules. On the contrary, he is more often than not himself a member of the dominant group (e.g. wealthy, white males), and shares the social background, education, perspective, and values of that group. As a result, his conceptions of the relevant contested concepts (e.g., equality or freedom of expression) will be their conceptions -- i.e. conceptions which serve the interests of the dominant groups against whom the constitution is meant to serve as protection. But if semantic meaning, intentions and Hercules' best theory are all at the mercy of dominant ideologies, then the kind of protections heralded by the idea of constitutionalism may be a myth, and a harmful one at that. So what is the solution according to critical theorists? The proffered solutions vary considerably from one critical theorist to the next, depending on how radical or skeptical the theorist tends to be. A revolutionary communist might advocate the complete overthrow of constitutional,

democratic government, while many liberal feminists are content to work within existing constitutional systems to eradicate the vestiges of patriarchy which have survived recent feminist movements.[15] But all seem to agree that progress can be made only if the myths surrounding constitutional protection -- the constraining force of meaning, intention, and objective moral theory -- are all exposed, and that the true political forces at work in constitutional practice are acknowledged and dealt with openly. Whether the idea of constitutionalism can survive the lessons of critical theory is a very good question.

Notes to Constitutionalism

Notes

1. Unless otherwise indicated, the term "constitutional" (and its cognate terms "constitutionalism", "constitution", and so on) should henceforth be understood to carry this richer meaning.

2. Whether Locke and Hobbes are properly invoked in this way is perhaps open to question. There is reason to believe that Locke's argument defends political, as opposed to strictly legal, limitations upon the sovereign. But as we shall see, constitutionalism seems to require legal limitation. It might be argued that *effective* political limitation requires legal limitation as well, but this does not seem strictly necessary. More on this later.

3. "For to be subject to laws is to be subject to the commonwealth - that is to the sovereign - that is, to himself, which is not subjection but freedom from the laws." (Leviathan, Ch. 29, 255)

4. What Parliament does "no authority upon Earth can undo." (Sir William Blackstone)

5. See Hart, *The Concept of Law*, pp 73-78. For Austin, see *The Province of Jurisprudence Determined*, Lecture VI.

6. *Leviathan*, Part 1, Ch. 13. Although Hobbes's sovereign is constitutionally unlimited, Hobbes insisted that individuals retained the right to self-preservation. It would be incoherent, Hobbes thought, for individuals to give up that right the protection of which is the very reason people have for creating a sovereign power. Although individuals retain the right to self-preservation, it is also true that Hobbes' unlimited sovereign has the right to take anyone's life if, in the sovereign's judgment, this is necessary to preserve the well being of the commonwealth.

7. Constitutional conventions are explored in Sec. 6 below. Although entrenchment is an almost universal characteristic of modern constitutions, and although one could plausibly argue that it is practically desirable, it may not be absolutely necessary. Some constitutional norms are ordinary statutes amenable to introduction and change by ordinary legislative procedures. Indeed, some constitutions are almost wholly statutory, e.g. the 1848 Italian Constitution and the constitution of New Zealand.

8. See, e.g., J. Rubenfeld, "Legitimacy and Interpretation."

9. As quoted in John Chipman Gray, "A Realist Conception of Law," p. 12.

10. It is arguable that the people of the United Kingdom, in virtue of their membership in the European Community and the fact that British Courts now enforce, as binding, Community law, have in fact relinquished their unlimited sovereignty. If the law of member states (e.g. France, Denmark, and the UK) must now be consistent with Community law, and the latter is immune from legislative change or repeal through legislative acts on the part of member governments, then it can be argued that the sovereignty of the member states within the European Community has been replaced by the sovereignty of "the people of Europe."

11. Henceforth, and unless otherwise indicated, all uses of the word "constitution" (and cognate terms) should be understood as referring to constitutional *law*.

12. Hercules is first introduced by Dworkin in Ch. 4 of *Taking Rights Seriously* and reappears in subsequent writings, most notable, *Law's Empire*.

13. Critical theories come in a variety of forms, the most influential ones being the Critical Legal Studies movement and feminist jurisprudence.

14. "I no longer believe that constitutional theory constrains, or is supposed to constrain judges. Rather...it serves primarily to provide a set of rhetorical devices that judges can deploy as they believe effective." (Mark Tushnet, "Constitutional Interpretation, Character and Experience, p. 759.)

15. See, e.g. Nadine Strossen, *Defending Pornography*.

Curry's Paradox

Curry's paradox, so named for its discoverer, namely Haskell B. Curry, is a paradox within the family of so-called paradoxes of self-reference (or paradoxes of circularity). Like the liar paradox (e.g., 'this sentence is false') and Russell's paradox, Curry's paradox challenges familiar naive theories, including naive truth theory (unrestricted T-schema) and naive set theory (unrestricted axiom of abstraction), respectively. If one accepts naive truth theory (or naive set theory), then Curry's paradox becomes a direct challenge to one's theory of logical implication or entailment. Unlike the liar and Russell paradoxes Curry's paradox is negation-free; it may be generated irrespective of one's theory of negation. An intuitive version of the paradox runs as follows.

Consider the following list of sentences, named 'The List':

1. Tasmanian devils have strong jaws.
2. The second sentence on The List is circular.
3. If the third sentence on The List is true, then *every sentence* is true.
4. The List comprises exactly four sentences.

Although The List itself is not paradoxical, the third sentence (a conditional) is. Is it true? Well, suppose, for conditional proof, that its antecedent is true. Then

> the third sentence of The List is true

is true. By substitution, it follows that

> If the third sentence of The List is true, then every sentence is true

is true. But, then, Modus Ponens on the above two sentences yields that

> every sentence is true

is true. So, by conditional proof, we conclude that

> If the third sentence of The List is true, then every sentence is true

is true. By substitution, it follows that

> the third sentence of The List is true

is true. But, now, by Modus Ponens on the above two sentences we get that

> every sentence is true

is true. By naive truth theory we disquote (or, in this case, dis-display, as it were) to conclude: Every sentence is true! So goes (one version of) Curry's paradox.

---

1. Brief History and Some Caveats

In 1942 Haskell B. Curry presented what is now called *Curry's paradox*. Perhaps the most intuitive version of the paradox is due to Arthur N. Prior (1955), who recast Curry's paradox as a "proof" of God's existence. (Let C = ‘If C is true then God exists’.) The version presented above is (in effect) Prior's version.

There are basically two different versions of Curry's paradox, a truth-theoretic (or proof-theoretic) and a set-theoretic version; these versions will be presented below. For now, however, there are a few caveats that need to be issued.

Caveat 1. *Loeb's Paradox*. Prior's version is (in effect) rehearsed by Boolos and Jeffrey (1989), where neither Prior nor Curry is given credit; rather, Boolos and Jeffrey point out the similarity of the paradox to reasoning used within the proof of Loeb's Theorem; and subsequent authors, notably Barwise & Etchemendy (1984), have called the paradox *Loeb's paradox*. While there is no doubt strong justification for the alternative name (given the similarity of Curry's paradox to the reasoning involved in proving Loeb's Theorem) the paradox does appear to have been first discovered by Curry.

Caveat 2. *Geometrical Curry Paradox (Jigsaw Paradox)*. This is *not* the same Curry paradox under discussion; it is a well-known paradox, due to *Paul* Curry, having to do with so-called geometrical dissection. (The so-called Banach-Tarski geometrical paradox is related to *Paul* Curry's geometrical

paradox.) See Gardner 1956 and Fredrickson 1997 for full discussion of *this* (geometrical) Curry paradox.

2. Curry's Paradox: Truth- and Set-Theoretic Versions

Truth-Theoretic Version

Assume that our truth predicate satisfies the following T-schema:

> *T-Schema*: $\mathrm{T}[A] \leftrightarrow A$,

where '[ ]' is a name-forming device. Assume, too, that we have the principle called *Assertion* (also known as *pseudo modus ponens*):

> *Assertion*: $(A \,\&\, (A \rightarrow B)) \rightarrow B$

(NB: We could also use the principle called *Contraction*: $((A \rightarrow (A \rightarrow B)) \rightarrow (A \rightarrow B)$.) Curry's paradox quickly generates *triviality*, the case in which everything is true.

By diagonalization, self-reference or the like we can get an arbitrary sentence, C, such that:

> $C \;=\; \mathrm{T}[C] \rightarrow \boldsymbol{F}$,

where $\boldsymbol{F}$ is anything you like. (For effect, though, make $\boldsymbol{F}$ something obviously false.) By an instance of the T-schema ('$\mathrm{T}[C] \leftrightarrow C$') we immediately get:

> $\mathrm{T}[C] \leftrightarrow (\mathrm{T}[C] \rightarrow \boldsymbol{F})$,

Again, using the same instance of the T-Schema, we can substitute C for T[C in the above to get (1):

1. $C \leftrightarrow (C \rightarrow \boldsymbol{F})$	[by T-schema and Substitution]
2. $(C \,\&\, (C \rightarrow \boldsymbol{F})) \rightarrow \boldsymbol{F}$	[by Assertion]
3. $(C \,\&\, C) \rightarrow \boldsymbol{F}$	[by Substitution, from 2]
4. $C \rightarrow \boldsymbol{F}$	[by Equivalence of C and $C\&C$, from 3]
5. C	[by Modus Ponens, from 1 and 4]
6. $\boldsymbol{F}$	[by Modus Ponens, from 4 and 5]

Letting $\boldsymbol{F}$ be anything entailing triviality Curry's paradox quickly "shows" that the world is trivial!

Set-Theoretic Version

The same result ensues within naive set theory. Assume, in particular, the (unrestricted) axiom of abstraction (or comprehension):

> *Unrestricted Abstraction*: $x \in \{y \mid A(y)\} \leftrightarrow A(x)$.

Moreover, assume that our conditional, $\rightarrow$, satisfies Contraction (as above), which permits the deduction of

> $(s \in s \rightarrow A)$

from

> $s \in s \rightarrow (s \in s \rightarrow A)$.

In the set-theoretic case, let $C =_{\mathrm{df}} \{x \mid x \in x \rightarrow \boldsymbol{F}\}$, where $\boldsymbol{F}$ remains as you please (but something obviously false, for effect). From here we reason thus:

1. $x \in C \leftrightarrow (x \in x \rightarrow \boldsymbol{F})$	[by Naive Abstraction]
2. $C \in C \leftrightarrow (C \in C \rightarrow \boldsymbol{F})$	[by Universal Specification, from 1]
3. $C \in C \rightarrow (C \in C \rightarrow \boldsymbol{F})$	[by Simplification, from 2]
4. $C \in C \rightarrow \boldsymbol{F}$	[by Contraction, from 3]
5. $C \in C$	[by Modus Ponens, from 2 and 4]
6. $\boldsymbol{F}$	[by Modus Ponens, from 4 and 5]

So, coupling Contraction with the naive abstraction schema yields, via Curry's paradox, triviality.

Significance, Solutions, and Open Problems

Significance

What is the significance of Curry's paradox? The answer depends on one's approach to paradox in general. Any comprehensive theory of language has to give some sort account of the paradoxes (e.g., the liar, or Russell's, or etc.). Classical approaches tend to fiddle with the T-schema (or naive abstraction) or reject the existence of certain (paradoxical) sentences. Such classical approaches tend to respond to Curry's paradox in the same fashion — by rejecting the existence of Curry sentences or fiddling with the unrestricted T-schema (or naive abstraction). Some popular variations of these two options include Gupta-

Belnap revision theory (1993), Tarski's familiar hierarchical theory (or Russellian type theory), Simmons's singularity theory (1993), Burge's indexical theory (1979), Kripke's fixed point semantics (1975), Gaifman's pointer semantics (1988), Barwise-Etchemendy situation-cum-Aczel-set-theory (1984), and others. (NB: These theories are quite different from each other; however, each of them fits under one of the two so-called classical options mentioned above; they either modify the naive T-schema or reject the existence of so-called strengthened liar sentences.) Where Curry's paradox becomes especially significant is not with classical approaches but rather with certain non-classical approaches; specifically, Curry's paradox is a direct challenge to any non-classical approach that attempts to preserve naive truth (or set) theory in full. Such approaches attempt to preserve naive truth (or set) theory, preserve the apparent existence of Curry sentences, and avoid the apparent non-triviality of the world. Satisfying these desiderata requires a paraconsistent logic, one that affords inconsistent but non-trivial theories. What Curry's paradox shows is that not just any old paraconsistent logic will do; in particular, on pain of triviality, no connective in the language can satisfy contraction or absorption and support the T-scheme or Naive comprehension scheme. Among other things, this constraint rules out quite a few popular candidates for implicative conditionals -- including, for example, various popular relevant conditionals, including those of ***E*** and ***R***.

A Solution

There is great interest in resolving the paradoxes in the sort of non-classical fashion suggested above. Such interest, coupled with Curry's paradox, has fostered ongoing interest in non-classical (paraconsistent) semantics for entailment. One area in which such research is growing is substructural logic. While there is no generally accepted (non-classical) solution to Curry's paradox one approach is particularly promising, an approach due to Graham Priest (1992) and based upon Kripke's invocation of non-normal worlds. (Kripke invoked such worlds for purposes of modeling Lewis systems weaker than *S4*, not for purposes of solving Curry's paradox.) The idea may be seen easily through its semantics, as follows.

Setting negation aside (for purposes of Curry), we assume a propositional language with the following connectives: conjunction (&), disjunction ($\vee$), and entailment ($\rightarrow$). (For purposes of resolving Curry's paradox, negation may be set aside; however, the current semantics allow for a variety of approaches to negation, as well as quantifiers.) An interpretation is a 4-tuple, (W,N,[ ], f), where W is a non-empty set of worlds (index points), N is a non-empty subset of W, [ ] is a function from propositional parameters to the powerset of W; we may, for convenience, see the range of [ ] as comprising propositions (sets of worlds at which various sentences are true), and so call the values of [ ] *propositions*. We let NN be the set of so-called non-normal worlds, namely $NN = W - N$. In turn, f is a function from (ordered) pairs of propositions to NN. Now, [ ] is extended to all sentences (A, B, ...) via the following clauses:

$[A\&B] = [A]\cap[B]$

$[A\vee B] = [A]\cup[B]$

The value of an entailment is the union of two sets: *N*, the class of normal worlds where the entailment is true, and *NN*, the of non-normal worlds where the entailment is true. Assuming the usual *S5* truth conditions, *N* and *NN* are specified thus:

$N = W$, if $[A] \subseteq [B]$; otherwise, $N = \varnothing$.

$NN = f([A],[B])$.

With all this in hand, validity is defined in the usual way: namely, as truth-preservation at all *normal* worlds of all interpretations.

Why restrict the definition merely to normal worlds? The explanation goes hand-in-hand with the informal interpretation of non-normal worlds; according to Priest's suggestion, non-normal worlds should be understood to be worlds where the laws of logic are different — different from the actual laws, where such laws are expressed by (true) entailment claims. Accordingly, since our definition of validity is an attempt to capture our (actual) logical laws, we need not, and should not, worry about worlds where the logical laws are different, at least not in our definition of validity. Such worlds, however, are otherwise very important; as one can easily verify, such worlds afford the usual logical laws (within the positive fragment at issue) but do not sanction the unwanted "laws" — e.g., Assertion and the like. In this way, one can enjoy naive truth theory (or naive set theory) without tripping into triviality as a result of Curry sentences.

Priest (1992) gives a sound and complete proof theory for the given semantics, but this is left for the reader to consult.

Open Issues and Problems

With the foregoing semantics one sneed not reject the existence of Curry sentences (which are difficult to reject when one's language is a natural language) or naive truth theory; however, there are various philosophical issues that need to be addressed, a few of which are canvassed below.

One philosophical issue confronting the given semantics is the very nature of such non-normal worlds. What are they? As intimated, Priest's suggestion is that they are simply (impossible) worlds where the laws of logic are different. But is there any reason, independent of Curry's paradox, to admit such worlds? Fortunately, the answer seems to be ‘yes’. One reason has to do with the common (natural language) reasoning involving counter-logicals, including, for example, sentences such as ‘If intuitionistic logic is correct, then double negation elimination is invalid’. Invoking non-normal worlds provides a simple way of modelling such sentences and the reasoning involving them.

Another objection also arises. Notice that, on the foregoing semantics, there are (non-normal) worlds where the law of simplification, i.e., $A \& B \rightarrow B$, is false; however, there is no world (normal or otherwise) at which we have a false *B* but true *A*&*B*. Likewise for all other worlds where the logical laws differ; the

worlds themselves, as it were, do not break the laws, even though the laws are false at such worlds. What explains this "lack of supervenience" at non-normal worlds? Priest himself offers no explanation, and the problem remains an open one. None the less, here is a suggestion (which has yet to be explored in print): What would it take for logical laws to fail? Most philosophers will agree that it is hard to imagine worlds in which there are events that contravene logical laws. My suggestion is that the only way for logical laws to fail is via arbitrary "fiat", as it were. No world (possible or otherwise) comprises events that refute, contravene, or otherwise show the actual logical laws to be false; what is required to falsify logical laws is mere arbitrariness; and such arbitrariness is precisely what one gets from the function, *f*. The suggestion, then, is simply this: For logical laws to fail at any world (and, hence, at non-normal worlds) one requires arbitrariness and thereby a lack of the supervenience at issue. Whether this suggestion solves the (philosophical) problem at hand is an (other) open problem.

There are other philosophical (and logical) problems that remain open. One of the most important recent papers discussing such problems is Restall's "Costing Non-Classical Solutions to Paradoxes of Self-Reference" (see Other Internet Resources). Restall shows that the sorts of non-classical approach discussed above must give up either transitivity of entailment, infinitary disjunction or distributive lattice logic (i.e., an infinitary disjunction operator distributing over finite conjunction); otherwise, as Restall shows, Curry's paradox arises immediately and triviality ensues. The importance of Restall's point lies not only in the formal constraints imposed on suitable non-classical approaches to Curry; its importance lies especially in the philosophical awkwardness imposed by such constraints. For example, one (formal) upshot of Restall's point is that, on a natural way of modelling propositions (e.g., in familiar world-semantics), some classes of propositions will not have disjunctions on the (given sort of) non-classical approach; the philosophical upshot (and important open problem) is that there is no known explanation for why such classes lack such a disjunction. (Needless to say, it is not a sufficient explanation to note that the presence of such a disjunction would otherwise generate triviality via Curry's paradox.)

The foregoing issues and open problems confront various non-classical approaches to paradox, problems that arise particularly sharply in the face of Curry's paradox. It should be understood, however, that such problems may remain pressing even for those who are firmly committed to classical approaches to paradox; for one might be interested not so much in *accepting* or *believing* such non-classical proposals but, rather, merely in using such proposals to model various naive but non-trivial theories — naive truth theory, naive set theory, naive denotation theory, etc.. One need not believe or accept such theories to have an interest in modeling them accurately. If one has such an interest, then the foregoing problems arising from Curry's paradox must be addressed. (See Slaney 1989, and the classic Meyer, Dunn, and Routley 1979, and also Restall 2000 for further discussion.)

Disjunction

Disjunction is a binary truth-function, the output of which is a sentence true if at least one of the input sentences (disjuncts) is true, and false otherwise. Disjunction, together with negation, provide sufficient means to define all other truth-functions. Its supposed connection with the *or* words of natural language has intrigued and mystified philosophers for many centuries, and the subject has inspired much creative myth-making, particularly since the advent of truth-tables early in the twentieth century. In this article some of those myths are set out and dispelled.

Introduction

A disjunction is a kind of compound sentence historically associated by English-speaking logicians and their students with indicative sentences compounded with *either* ... *or*, such as

> Either I am very rich or someone is playing a cruel joke.

But nowadays the term *disjunction* is more often used in reference to sentences (or well-formed formulae) of associated form occurring in formal languages. Logicians distinguish between

> (a) the abstracted *form* of such sentences and the roles that sentences of that form play in

arguments and proofs,

(b) the *meanings* that must be assigned to such sentences to account for those roles.

The former represents their *syntactic* and *proof-theoretic* interests, the latter their *semantic* or *truth-theoretic* interest in disjunction. Introductory logic texts are sometimes a little unclear as to which should provide the defining characteristics of disjunction. Nor are they clear as to whether disjunctions are primarily features of natural or of formal languages. Here we consider formal languages first.

Syntax

The definition of a formal system, either axiomatic or natural deductive, requires the definition of a language, and here the formal vocabulary of disjunction makes its first appearance. If the disjunctive constant $\vee$ (historically suggestive of Latin *vel* (*or*)) is a primitive constant of the language, there will be a clause, here labeled [$\vee$] in the inductive definition of the set of well-formed formulae (wffs). Using α and β as metalogical variables, ranging over wffs, such a clause would read:

[$\vee$] If α is a wff and β is a wff, then $\alpha \vee \beta$ is a wff

perhaps accompanied by an instruction that $\alpha \vee \beta$ is to be referred to as the *disjunction* of the wffs α and β, and read as "[name of first wff] vel (or 'vee', or 'or') [name of second wff]". Thus, on this instruction, the wff $p \vee q$ is the *disjunction* of p and q, and is pronounced as 'pea vel queue' or 'pea vee queue' or 'pea or queue'. In this case, p and q are the disjuncts of the disjunction.

If $\vee$ is a non-primitive constant of the language, then typically it will be introduced by an abbreviative definition. In presentations of classical systems in which the conditional constant $\rightarrow$ or $\supset$ and the negational constant $\neg$ are taken as primitive, the disjunctive constant $\vee$ might be introduced in the abbreviation of a wff $\neg\alpha \rightarrow \beta$ (or $\neg\alpha \supset \beta$) as $\alpha \vee \beta$. Alternatively, if the conjunctive & has already been introduced either as a primitive or as a defined constant, $\vee$ might be introduced in the abbreviation of a wff $\neg(\neg\alpha \,\&\, \neg\beta)$ as $\alpha \vee \beta$.

Proof Theory

Much as we would understand the conversational significance of vocabulary more generally if we had a complete set of instructions for initiating its use in a conversation, and for suitable responses to its introduction by an interlocutor, we give the proof-theoretic significance of a connective by providing rules for its introduction into a proof and for its elimination. In the case of $\vee$, these might be the following:

[$\vee$-introduction] For any wffs α and β, a proof having a subproof of α from an ensemble

Σ of wffs, can be extended to a proof of $\alpha \vee \beta$ from Σ.

[$\vee$-elimination] For any wffs α, β, γ, a proof that includes

- a subproof of $\alpha \vee \beta$ from an ensemble of wffs Σ,
- a subproof of γ from an ensemble $\Delta \cup \{\alpha\}$, and
- a subproof of γ from an ensemble $\Theta \cup \{\beta\}$,

can be extended to a proof of γ from $\Sigma \cup \Delta \cup \Theta$.

Intuitively, the former would correspond to a rule of conversation that permitted us to assert *A* or *B* (for any *B*) given the assertion that *A*. Thus if we are told that Nicholas is in Paris, we can infer that Nicholas is either in Paris or in Toulouse.

Intuitively, the latter rule would correspond to a rule that, given the assertion that *A* or *B*, would permit the assertion of anything that is permitted both by the assertion of *A* and by the assertion of *B*. For example, given the assertion on certain grounds that Nicholas is in Paris or Toulouse, we are warranted in asserting on the same grounds plus some geographical information, that Nicholas is in France, since that assertion is warranted (a) by the assertion that Nicholas is in Paris together with some of the geographical information and (b) by the assertion that Nicholas is in Toulouse together with the rest of the geographical information. More generally we may sum the matter up by saying that the rule corresponds to the conversational rule that lets us extract information from an *or*-sentence without the information of either of its clauses. In the example, we are given the information that Nicholas is in Paris or Toulouse, but we are given neither the information that Nicholas is in Paris nor the information that he is in Toulouse.

Semantics

In its simplest, classical, semantic analysis, a disjunction is understood by reference to the conditions under which it is true, and under which it is false. Central to the definition is a *valuation*, a function that assigns to every atomic, or unanalysable sentence of the language a value in the set {1, 0}. In general the inductive truth-definition for a language corresponds, clause by clause to the definition of its well-formed formulae. Thus for a propositional language it will take as its basis, a clause according to which an atom is true or false accordingly as the valuation maps it to 1 or to 0. In systems in which $\vee$ is a primitive constant, the clause corresponding to disjunction takes $\alpha \vee \beta$ to be true if at least one of α, β is true, and takes it to be false otherwise. Where $\vee$ is introduced by either of the definitions earlier mentioned, that truth-condition can be computed for $\alpha \vee \beta$ from those of the conditional ($\rightarrow$ or $\supset$) or conjunction (&) and negation ($\neg$).

Now the truth-definition can be regarded as an extension of the valuation from the atoms of the language to the entire set of wffs with 1 understood as the truth-value, true, and 0 understood as the truth-value,

false. Thus, classically, disjunction is semantically interpreted as a binary truth-function from the set of pairs of truth-values to the set {0, 1}. The tabulated graph of this function, as dictated by the truth-definition, is called the truth-table for disjunction. That table is the following:

α β	$\alpha \vee \beta$
1 1 1 0 0 1 0 0	1 1 1 0

Inclusive and Exclusive disjunctions

Authors of introductory logic texts generally take this opportunity to distinguish the disjunction we have been discussing from another binary truth-function $\veebar$ whose graph is tabulated by the table:

α β	$\alpha \veebar \beta$
1 1 1 0 0 1 0 0	0 1 1 0

where $\alpha \veebar \beta$ is read α *xor* β. This truth-function is referred to variously as exclusive disjunction, as 0110 disjunction (after the succession of values in its main column), and as logical difference. The wff $\alpha \veebar \beta$ is true when exactly one of α, β is true; false otherwise. To make matters explicit, the earlier discussed truth-function $\vee$ is called inclusive, or non-exclusive or 1110 disjunction.

Natural Language

It is an assumption, at any rate a claim, of many textbook authors that there are both uses of *or* in English that correspond to 1110 disjunction and uses that correspond to 0110 disjunction, and this supposition generally motivates the introduction and discussion of the xor connective. Since we are following the usual order of textbook exposition, this is perhaps the moment to make a few observations on this score. The first are purely syntactic. The *or* of English that such authors cite is a coordinator (or coordinating conjunction). It can coordinate syntactic elements of virtually any grammatical type, not merely whole sentences. Moreover, if we consider only its uses joining whole sentences, we must notice that it can join sentences of virtually any mood: interrogative sentences and imperatives as well as indicative sentences can be joined by *or* in English. And again, if we restrict our attention to its uses joining indicative sentences, we must note that *or* is by no means restricted to the binary cases in this role. Indeed, there is

no theoretical finite limit to the number of clauses that it can join. This is perhaps the most fundamental relevant syntactic difference between *or* on the one hand and $\vee$ and $\veebar$ on the other. The sentence

> Nathalie has been and gone or Nathalie will arrive today or Nathalie will not arrive at all

is a perfectly correct sentence and not ambiguous as between

> (Nathalie has been and gone or Nathalie will arrive today) or Nathalie will not arrive at all

and

> Nathalie has been and gone or (Nathalie will arrive today or Nathalie will not arrive at all).

By contrast, the wff $p \vee q \vee r$, far from being ambiguous as between $(p \vee q) \vee r$ and $p \vee (q \vee r)$, is, on the inductive definition of well-formedness, not a wff. If the parenthesis-free notation is tolerated in general logical exposition, this is because $\vee$ is *associative*, that is, the wffs $(p \vee q) \vee r$ and $p \vee (q \vee r)$ are syntactically interderivable, and semantically have identical truth-conditions. The formal account of disjunction could readily be liberalized to accommodate that fact, and even conveniently in languages in which $\vee$ was primitive. In that case our inductive definition of the language could permit any such string as $\vee(\alpha_1, \ldots, \alpha_i, \ldots, \alpha_n)$ to be well-formed if $\alpha_1, \ldots, \alpha_i, \ldots$ and α_n are. The relevant clause of the truth-definition would accordingly be modified in such a way as to give $\vee(\alpha_1, \ldots, \alpha_i, \ldots, \alpha_n)$ the maximum of the truth-values of $\alpha_1, \ldots, \alpha_i, \ldots$ and α_n. Moreover, this accords well with such cases as the one cited in which *or* joins more than two simple clauses: such a sentence is true if at least one of its clauses is true; false otherwise.

The fact that English *or* is not binary does not accord so well with the claim made by many textbook authors that there are uses of *or* that require representation by 0110 disjunction. To be sure, $\veebar$ is associative, so that a notational liberalization would be possible, parallel to the one described for $\vee$. But, as Hans Reichenbach seems first to have pointed out (in Reichenbach [1947]), the truth-definition for $\veebar(\alpha_1, \ldots, \alpha_i, \ldots, \alpha_n)$ would have to be such as to give it the value 1 if any odd number of $\alpha_1, \ldots, \alpha_i, \ldots, \alpha_n$ have the value 1; the value 0 otherwise. The result is evident from the truth-table where $n > 2$. For $n = 3$, suppose that $\alpha \veebar \beta \veebar \gamma$ has the value 1. The truth-definition as given by the table requires that exactly one of $\alpha \veebar \beta, \gamma$ has the value 1. Let γ have the value 1; then $\alpha \veebar \beta$ has the value 0. Then α and β have the same value. That is, either both α and β have the value 0, or both α and β have the value 1. In the former case exactly one of α, β, γ has the value 1; in the latter, all three have the value 1. That is, the disjunction will take the value 1 if and only if an odd number of disjuncts have the value 1. A simple induction will prove that this result holds for an exclusive disjunction of any finite length. It is sufficient for present purposes to note that, in the case where $n = 3$, $\veebar(\alpha_1, \alpha_2, \alpha_3)$ will be true if all of its disjuncts are true. Now there is no naturally occurring coordinator in any natural language matching the truth-conditional profile of such a connective. There is certainly no use of *or* in English in accordance with which five sentences *A*, *B*, *C*, *D*, and *E* can be joined to form a sentence *A* or *B* or *C* or *D* or *E*, which is

true if and only if either exactly one of the component sentences is true, or exactly three of them are true or exactly five of them are true.

Most of the texts make no claims about exclusive disjunctive uses of either English or Latin *or*-words beyond the two-disjunct case. But it is a fair presumption that the belief in exclusive disjunctive uses of *or* in English includes just such three-disjunct uses of *or*. Such a use of *or*, would be one in accordance with which three sentences *A*, *B*, and *C* can be joined to form a sentence *A* or *B* or *C*, which is true if and only if exactly one of the component sentences is true. Though not a 0110-disjunctive use of *or*, this would be a general use representable as 0110 disjunction in the two-disjunct case.

The question as to whether there is such a use of *or* in English, or any other natural language goes to the very heart of the conception of truth conditional semantics. For it seems certain that there are conversational uses of *or* that invite the inference of exclusivity, but which do not seem to require exclusivity for their truth. Thus, for example, if one says (as in Tarski [1941], 21) 'We are going on a hike or we are going to a theater', even with charged emphasis upon the *or*, one will have spoken falsely if in the event we do both, unless, as in Tarski's example, one has also denied the conjunction.

Some authors have sought examples of 0110 disjunction in *or*-sentences whose clauses are mutually exclusive. For example, Kegley and Kegley discuss the case (Kegley and Kegley [1978], 232):

> John is at the play, or he is studying in the library

of which the authors remark, "There is no mistaking the sense of *or* here: John cannot be in both places at once". If their example were an example of exclusive disjunction, we could safely infer from it that the play is not being performed in the library, that the theatre is not in the library, that John is not swotting in the stalls between acts while his companion fights her way to the bar to fetch the drinks. In fact, even, perhaps particularly, when the disjuncts are genuinely mutually exclusive, there are no grounds for the supposition that the *or* represents 0110 disjunction. Were there such grounds the $\vee$ of formal logic would require distinct semantic accounts for the wffs $p \vee q$ and $p \vee \neg p$. As Barrett and Stenner point out (Barrett and Stenner [1971]), the case requires quite the reverse. Since the truth-tables of $\vee$ and $\veebar$ differ exactly in the output value of the first row, what alone would clinch the case for the existence of an exclusive *or* would be a sentence in which both disjuncts were true, and the disjunction therefore false. No author has yet produced such an example.

The Myth of *Vel* and *Aut*

If the logic texts dictate the structure and content of our discussion, it is perhaps as well to dispel another current myth -- namely that the notational choice of $\vee$, (read as *vel*) as the connective of inclusive disjunction, and the claim that the English *or* has 0110-disjunctive uses are supported by the facts of the Latin language. I. Copi is as explicit as any (Copi [1971], 241):

> The Latin word "vel" expresses weak or inclusive disjunction, and the Latin word "aut" corresponds to the word "or" in its strong or exclusive sense.

The idea is, first, that whereas English has only one *or*-word, Latin has two: *vel* and *aut*, and secondly, that the uses of *vel* in Latin would be representable as 1110 disjunction and the uses of *aut* as 0110 disjunction. As to the first, the very shape of the claim is likely to mislead. The case is not that Latin had two words for *or*, but rather that Latin had more than one word that gets translated into English as *or*. In fact, Latin had *many* words that are translated into English as *or*, including, besides the two listed, at least *seu*, *sive* and the enclitic *ve*. So does English have many words that can be translated into English as *or*, including *unless*, *if ... not*, *but* (It does not rain but it pours) and so on. All vocabulary has a history, and languages accumulate vocabulary that becomes adapted to nuanced uses.

Now the supposition that Latin had a 0110 coordinator must suffer from the same implausibilities as the corresponding supposition about English. What of the two-disjunct case? If any general tendency can be detected in actual Latin usage, say in the classical period, that would distinguish the uses of *vel* from those of *aut*, it is that *aut* tended to be brought into use in the formation of lists of disjoint or contrasted or opposed items, categories or classes or states, as for example

> *Omne enuntiatum aut verum aut falsum est* [Every statement is either true or false] (Cicero, *De Fato*, 222).

The difficulty with these examples is that the exclusiveness of the states independendently of the choice of connective must mask any disjointness that the connective could itself impose. That it does not impose *any* disjointness itself is best seen in its list-forming uses. Consider the list (Cicero, *De Officiis*):

> *tribunos aut plebes* [the magistrates or the mob, (*accusative plural*)]

to be sure the categories are disjoint, and this fact might be supposed to contribute to the selection of *aut*. But the mutual exclusion in such cases need not survive the addition of a verb.

> *Timebat tribunos aut plebes* [one feared the magistrates or the mob]

does not exclude the case in which one feared both. However, what clinches the refutation of this mythical supposition is that if that whole clause is brought within the scope of a negator, the resulting sentence will expect a reading along the lines of 1110 disjunction.

> *Nemo timebat tribunos aut plebes* [No one feared the magistrates or the mob]

just means no one feared either. It does not mean everyone either feared neither or feared both. Since the negation of a 0110 disjunction is a 1110 disjunction (either both disjuncts are true or both disjuncts are false), this use of *aut* cannot be a 0110 disjunctive use.

In fact, in classical Latin, *aut* was favoured over *vel* in constructions involving negations, and in that use, *aut* behaves analogously to ⊻. But pretty well anywhere an *aut* could be used, a *vel* could be substituted, and vice versa. The resulting sentence would have a different flavour, and in some instances would be mildly eccentric, but would not have a different truth condition. The uses of *vel* reflected its origins as an imperative form of *volo*. The flavour of

> *Nemo timebat vel tribunos vel plebes*

would be closer to that of

> Name which group (of the two) you will: no one feared them.

Aut was adversative: no one feared either social extremity. (For more examples and a more detailed discussion, see Jennings [1994], 239-251.)

The *Or* of Natural Language

There are undoubtedly disjunctive uses of *or* in English, and of corresponding vocabulary in other natural languages. But the uses of *or* after the pattern of the logic texts:

> Either Argentina will boycott the conference or the value of lead will diminish

and so on constitute only a very small proportion, certainly fewer than 5% of the occurrences of *or* in English, and, it can be supposed, of corresponding words in all other natural languages as well. It is therefore not surprising that it should be some of these non-disjunctive uses that have been misidentified as instances of exclusive disjunction. The example cited (in Richards [1978], 84) is a good representative example of one such common misidentification:

> So how can we find a clear-cut case of the exclusive ‘or’? Imagine a boy who asks for ice cream *and* strawberries for tea. He is told as a sort of refusal:
>
> > ’You can have ice cream *or* strawberries for tea’.
>
> Here there is no doubt: not both may be had.

Once again there is a difficulty in trying to account for the exclusivity by reference to truth-conditions, though, if we are permitted to consult the intentions of the speaker (as Richards himself does) we may be in no doubt as to the prohibition of strawberries and icecream, however curious such a prohibition might seem. But this example, in company with the many others like it (which this author has sometimes referred to collectively as *the argument from confection*) suffers from the even more serious flaw that it

is not a disjunction at all. The problem is not that the *or* does not join whole clauses. Even if we expand the example to

> ’You can have ice cream for tea *or* you can have strawberries for tea’,

the sentence cannot be construed as a disjunction. The reason is that the child would be correct in inferring that he can have ice cream for tea, and would be correct in inferring that he can have strawberries for tea. Such sentences are elliptical for conjunctions, not for disjunctions, even on a truth-conditional construal. It just happens that for such conjunctions, questions of exclusivity, or rather non-combinativity also arise.

Not every *or* of English (nor every counterpart of *or* in other languages) is disjunctive, even among those that join pairs of indicative sentences.

Legal Punishment

The question of whether, and how, legal punishment can be justified is central to both legal and political philosophy: what could justify a state in using the apparatus of the law to inflict burdensome sanctions on its citizens? Radically different answers to this question are offered by consequentialist and by retributivist theorists -- and by those who seek to combine consequentialist with retributivist considerations in ‘mixed’ theories of punishment; an important strand in recent theorising has been the idea of punishment as a communicative enterprise. Meanwhile, abolitionist theorists argue that we should aim to replace legal punishment rather than to justify it.

1. Legal Punishment and its Justification

The central question asked by philosophers of punishment is: What can justify punishment? More precisely, since they do not usually talk much about punishment in such contexts as the family or the workplace, their question is: What can justify formal, legal punishment imposed by the state on criminals? We will also focus on legal punishment here: not because the other species of punishment do not raise important normative questions (they do), nor because such questions can be answered in terms of an initial justification of legal punishment as being the paradigm case (since it's not clear that they can be), but because legal punishment, apart from being more dramatically coercive and burdensome than other species of punishment usually are, raises distinctive issues about the role of the state and its

relationship to its citizens, and about the role of the criminal law. Future references to ‘punishment’ should therefore be read, unless otherwise specified, as references to legal or criminal punishment.

What then are we to justify in justifying punishment? The search for a precise definition of punishment that exercised some philosophers (for discussion and references see Scheid 1980) is likely to prove futile: but we can say that legal punishment involves the imposition of something that is intended to be burdensome or painful, on a supposed offender for a supposed crime, by a person or body who claims the authority to do so. How can such a practice, which infringes the freedom of those subjected to it, which not only causes but aims to cause them suffering, be justified?

We should not assume, however, that there is only one question of justification, which can receive just one answer. As Hart famously pointed out (Hart 1968: 1-27), we must distinguish at least three justificatory issues. First, what is the ‘general justifying aim’ of a system of punishment: what justifies the creation and maintenance of such a system -- what good does it achieve, what duty does it fulfil? Second, who may properly be punished: what principles or aims should determine the allocations of punishments to individuals? Third, how should the appropriate amount of punishment be determined: how should sentencers go about deciding how severe a sentence they should impose? We can add a fourth issue, which is insufficiently discussed by philosophers: what concrete modes of punishment are appropriate, in general or for particular crimes? It might of course turn out that answers to all these questions will flow from a single theoretical foundation -- for instance from a unitary consequentialist principle specifying the good that punishment should achieve, or from some version of the retributivist principle that the sole proper aim of punishment is to impose on the guilty the suffering they deserve. But, in this as in other matters of normative political theory, matters might not be as easy and simple as that: we might find that quite different and conflicting values are relevant to different issues about punishment; and that any complete normative account of punishment will have to find a place for these values -- and to help us find some no doubt uncomfortable compromises between them when they conflict.

Even this way of putting the matter oversimplifies it, by implying that we can hope to find a ‘complete normative account of punishment’: an account, that is, of how punishment can be justified. That is certainly an implicit assumption of much philosophical and legal discussion: punishment can -- of course -- be justified, and the theorists' task is to establish and explicate that justification. But it is an illegitimate assumption: normative theorists must be open to the possibility, startling and disturbing as it might be, that this pervasive human practice cannot be justified. Nor is this merely the kind of fantastical scepticism that moral philosophers are sometimes prone to imagine (‘suppose someone denied that killing for pleasure was wrong’): there is a significant strand of ‘abolitionist’ penal theorising (to which insufficient attention is paid in the philosophical literature) which argues precisely that legal punishment cannot be justified and should be abolished. The abolitionist claim is not merely that our existing penal practices are not justified: viewed in the light of many normative penal theories (one might almost say, of any plausible normative penal theory) our existing penal practices, especially those involving imprisonment, are not merely imperfect, but so radically inconsistent with the values that should inform a practice of punishment that they cannot claim to be justified. For those who think that punishment can in principle be justified, this means simply (and hardly surprisingly) that our penal practices need radical reform if they are to become justified: but the abolitionist critique goes much deeper than that, to argue that legal

punishment cannot be justified even in principle (see e.g. Christie 1977, 1981; Hulsman 1986, 1991; Bianchi & van Swaaningen 1986; de Haan 1990; Bianchi 1994. For a critical survey see Duff 1996: 67-87).

We will attend to some abolitionist arguments in what follows. Even if those arguments can be met, even if legal punishment can be justified, at least in principle, the abolitionist challenge is one that must be met, rather than ignored; and it will help to remind us of the ways in which any practice of legal punishment is bound to be morally problematic.

2. Punishment, Crime and the State

Legal punishment presupposes crime as that for which punishment is imposed, and a criminal law as that which defines crimes as crimes; and a system of criminal law presupposes a state, which has the political authority to make and enforce the law and to impose punishments. A normative account of legal punishment and its justification must thus at least presuppose, and should perhaps make explicit, a normative account of the criminal law (why should we have a criminal law at all?) and of the proper powers and functions of the state (by what authority or right does the state make and declare law, and impose punishments on those who break it?).

How far it matters, in this context, to make explicit a political theory of the state depends on how far different plausible political theories will generate very different accounts of how punishment can be justified and should be used. We cannot pursue this question here (for two sharply contrasting views on it, see Philips 1986, Davis 1989), but should look briefly at the concept of crime, since that is one focus of the abolitionist critique of punishment.

On a simple positivist view of law, crimes are kinds of conduct that are prohibited, on pain of threatened sanctions, by the law; and for positivists like Bentham, who combine positivism with a normative consequentialism, the questions of whether we should maintain a criminal law at all, and of what kinds of conduct should be criminalised, are to be answered by trying to determine whether and when this method of controlling human conduct is likely to produce a net increase in good. Such a perspective seems inadequate, however: inadequate both to the claims of the criminal law, which presents its demands as something other or more than those of a gunman writ large -- as something other or more than ‘Behave thus, or else!’; and to the normative issues at stake when we ask what kinds of conduct should be criminalised. For the criminal law portrays crime not merely as conduct which has been prohibited, but as a species of wrongdoing: whether our inquiry is analytical (into the concept of crime) or normative (as to what kinds of conduct, if any, should be criminal), we must therefore focus on that notion of wrongdoing.

Crimes are, at least, socially proscribed wrongs -- kinds of conduct which are condemned as wrong by some purportedly authoritative social norm. That is to say that they are wrongs which are not merely ‘private’ affairs, which properly concern only those directly involved in them: the community as a whole -- in this case the political community speaking through the law -- claims the right to declare them to be wrongs. But crimes are ‘public’ wrongs in a sense that goes beyond this. Civil law deals in part with

wrongs which are non-private in that they are legally and socially declared as wrongs -- with the wrong constituted by libel, for instance: but they are still treated as ‘private’ wrongs in the sense that it is up to the person who was wronged to seek legal redress. She must decide to bring, or not to bring, a civil case against the person who wronged her; and although she can appeal to the law to protect her rights, the case is still between her and the defendant. By contrast, a criminal case is between the whole political community -- the state or the people -- and the defendant (or, in politically backward polities such as Britain, between the monarch and the defendant): the wrong is ‘public’ in the sense that it is one for which the wrongdoer must answer not just to the individual victim, but to the whole polity through its criminal courts.

It is notoriously difficult to give a clear and plausible account of the distinction between civil and criminal law, between ‘private’ and ‘public’ legal wrongs, whether our interest is in the analytical question of what the distinction amounts to, or in the normative question of which kinds of wrong should fall into which category (see Murphy & Coleman 1984, ch. 3; a symposium in Boston University Law Review vol. 76 (1996): 1-373). It might be tempting to say that crimes are ‘public’ wrongs in the sense that they injure the whole community: they threaten social order, for instance, or cause ‘social volatility’ (Becker 1974); or they involve taking unfair advantage over those who obey the law (Murphy 1973); or they undermine the trust on which social life depends (Dimock 1997). But such accounts distract our attention from the wrongs done to the individual victims that most crimes have, when it is those wrongs that should be our central concern: we should condemn the rapist or murderer, we should see the wrong he has done as our concern, because of what he has done to his victim. Another suggestion is that ‘public’ wrongs are those which flout the community's essential or most basic values, in which all members of the community should see themselves as sharing: the wrong is done to ‘us’, not merely to its individual victim, in the sense that we identify ourselves with the victim as a fellow citizen (see Marshall & Duff 1998).

Abolitionists, however, sometimes argue that we should seek to eliminate the concept of crime from our social vocabulary: we should talk and think not of ‘crimes’, but of ‘conflicts’ or ‘troubles’ (Christie 1977; Hulsman 1986). One motivation for this might be the thought that ‘crime’ entails punishment as the appropriate response: but that is not so, since we could imagine a system of criminal law without punishment. To define something as a ‘crime’ does indeed imply that some kind of public response is appropriate, since it is to define it as a kind of wrong that properly concerns the whole community: but that public response could consist in nothing more than, for instance, some version of a criminal trial which calls the alleged wrongdoer to answer for her alleged wrongdoing, and condemns her for it, through a criminal conviction, if she is proved guilty. One can of course count a criminal conviction as a kind of punishment: but it does not entail the kind of punishment, imposed after conviction, with which penal theorists are primarily concerned.

Another possible motivation for the abolitionist objection to the concept of crime is a kind of moral relativism which objects to the ‘imposition’ of values on those who might not share them (Bianchi 1994: 71-97): but since abolitionists are very ready to tell us, insistently, how we ought to respond to conflicts or troubles, and how a state ought or ought not to treat its citizens, such an appeal to relativism reflects serious confusion (see Williams 1976: 34-39).

Another abolitionist concern is that by defining and treating conduct as 'criminal', the law 'steals' the conflicts which crime involves from those to whom they properly belong (Christie 1977): instead of allowing, and helping, those who find themselves in conflict to resolve their trouble, the law takes the matter over and translates it into the professionalised context of the criminal justice system, in which neither 'victim' nor 'offender' is allowed any appropriate or productive role. We will look later at the suggestion, which arises from this kind of view, that our response to crimes should consist not in punishment, but in a process of mediation or 'restoration' between victim and offender: all we need note here is that at least sometimes it is important to insist that the situation involves not just people in 'conflict', but a victim who has been wronged and an offender who has done the wrong. Faced, for instance, by feuding neighbours who persistently accuse each other of more or less trivial wrongs, it might indeed be appropriate to suggest that they should forget about condemning each other and look for a way of resolving their conflict. But faced by a rapist and the person he raped, or by a violent husband and the wife he has been beating up, it would a betrayal both of the victim and of the values to which we are supposedly committed to portray the situation merely as a 'conflict' which the parties should seek to resolve: whatever else or more we can do, we must recognise and declare that here is a victim who has been seriously wronged; and we must be ready to censure the offender's action as a wrong.

However, to argue that we should retain the concept of crime, that we should maintain a criminal law which defines and condemns a category of 'public' wrongs, is not yet to say that we should maintain a penal system which punishes those who commit such wrongs; as I have noted, while a system of criminal law might require something like a system of criminal trials which will authoritatively identify and condemn criminal wrongdoers, it does not of its nature require the imposition of further sanctions on such wrongdoers. So we must turn at last to the question of what could justify such a system of punishment.

3. Pure Consequentialism and Punishment

Many people, including those who do not take a consequentialist view of other matters, think that any adequate justification of punishment must be basically consequentialist. For we have here a practice which inflicts, indeed seeks to inflict, significant hardship or pain: how else could we hope to justify it than by showing that it brings consequential benefits sufficiently large to outweigh, and thus to justify, that hardship and pain? However, when we try to flesh out that simple consequentialist thought into something closer to a full normative account of punishment, problems begin to appear.

A consequentialist must justify punishment (if she is to justify it at all) as a cost-effective means to certain independently identifiable goods. Whatever account she gives of the final good or goods at which all action ultimately aims, the most plausible immediate good that a system of punishment can bring is the prevention of crime: a rational consequentialist system of law will define as criminal only conduct that is in some way harmful; in preventing crime we will thus be preventing the harms that crime causes; and punishment can prevent crime by incapacitating, or deterring, or reforming potential offenders.

It is a contingent question whether punishment can be an efficient method of preventing crime in any of these ways, and some objections to punishment rest on the empirical claim that it cannot be -- that there

are other and more efficient methods of crime-prevention, for instance those involving a therapeutic approach to offenders (see Wootton 1963; Menninger 1968). Our focus here, however, must be on the moral objections to consequentialist accounts of punishment -- on objections to the effect that crime-preventive efficiency does not suffice to justify a system of punishment.

The most familiar objections to consequentialist penal theories are objections to purely consequentialist theories which hold that only the consequences are relevant to question of justification (for two simple examples of such theories, see Wilson 1983; Walker 1991). For, critics argue, it could turn out that manifestly unjust punishments (the punishment of those known to be innocent, for instance, or excessively harsh punishment of the guilty) would efficiently serve the aim of crime prevention, and consequentialists must then regard such punishments as in principle justified: but they would be wrong, just because they would be unjust (see e.g. Hart 1968, chs. 1-2; Ten 1987; Primoratz 1999, chs. 2-3).

There are some equally familiar consequentialist responses to this familiar objection. One is to argue that such ‘unjust’ punishments would be justified if they would really produce the best consequences (see e.g. Smart 1973: 69-72; Bagaric & Amarasekara 2000) -- to which the critic will reply that we cannot thus put aside the moral significance of injustice. Another is to argue that in the real world it is extremely unlikely that such punishments would ever be for the best, and even less likely that the agents involved could be trusted reliably to pick out those rare cases in which they would be: thus we, and especially our penal officials, will do best if we think and act as if such punishments are intrinsically wrong and unjustifiable (see e.g. Rawls 1955; Hare 1981, chs. 3, 9.7) -- to which the critic will respond that this still makes the wrongness of punishing a known innocent contingent on its effects, and fails to recognise the intrinsic wrong that such punishment does (see e.g. Duff 1986: 151-64; Primoratz 1999, chs. 3.3, 6.5). Another response is to argue that a richer or subtler account of the ends that the criminal law should serve will generate suitable protection against unjust punishments (see Braithwaite & Pettit 1990, especially 71-6, on ‘dominion’ as the end of criminal law): but the objection remains that any purely consequentialist account will make the protection of the innocent against injustice contingent on its instrumental contribution to the system's aims (on Braithwaite & Pettit, see von Hirsch & Ashworth 1992; Duff 1996: 20-25; Pettit 1997).

4. Side-Constrained Consequentialism and Punishment

The most familiar response to such objections is to abandon pure consequentialism, in favour of a side-constrained consequentialism: to insist that the positive justification of any system of punishment -- its ‘general justifying aim’ (Hart 1968: 8-11) -- lies in its beneficial effects, but to argue that our pursuit of that aim is subject to non-consequentialist constraints which forbid, for instance, the deliberate punishment of the innocent, or the excessively harsh punishment of the guilty. (See most famously Hart 1968, and Scheid 1997 for a sophisticated Hartian theory; on Hart see Lacey 1988: 46-56; Morison 1988; Primoratz 1999, ch. 6.6.)

One question about such accounts concerns the grounding of these side-constraints. If they are derived from a ‘negative’ retributivism which insists that punishment is justified only if it is deserved (see Dolinko 1991: 539-43), they face the problem of explaining this retributivist notion of desert (see s. 4 below): but it is not clear whether they can be justified without such an appeal to retributivist desert (see Hart 1968: 44-48; Walker 1991, ch. 11; Feinberg 1988: 144-55). Even if such side-constraints can be securely grounded, however, consequentialist theories of punishment face further objections, focused on the moral character of punishment within those constraints. For the side-constrained consequentialist, so long as punishment is deserved it may and should be used to serve consequentialist ends -- most obviously the end of crime prevention: but, the critic now objects, to use punishment thus is to use those who are punished ‘merely as means’ to those further ends, which is to deny them the respect, the moral standing, that is their due as responsible agents (see Murphy 1973: 218). Objections to purely consequentialist theories often focused on the rights of the innocent: the objections to side-constrained consequentialism, which clearly protects the rights of innocent, focus on the rights or moral standing of the guilty.

The Kantian prohibition on treating each other ‘merely as means’ is admittedly unclear in its implications; and it can be argued that if punishment is reserved for those who voluntarily break the law, it does not treat them merely as means (see Walker 1980: 80-85). But a version of it does seem to have force against purely reformative punishments that aim simply so to modify offenders' dispositions that they will in future willingly obey the law; against purely incapacitative punishments that aim simply to prevent offenders from committing further crimes; and against purely deterrent punishments that aim simply to give potential offenders prudential reason to obey the law. For, the Kantian can argue, if we are to treat another ‘as an end’, with the respect due to her as a rational and responsible agent, we must seek to modify her conduct only by offering her good and relevant reasons to modify it for herself. These modes of purely consequentialist punishment, however, do not satisfy that demand. A purely reformative system treats those subjected to it not as rational, self-determining agents, but as objects to be re-formed by whatever efficient (and humane) techniques we can find. A purely incapacitative system does not leave those subjected to it free, as responsible agents should be left free, to determine their own future conduct, but seeks to pre-empt their future choices by incapacitating them. And although a purely deterrent system does, unlike the others, offer potential offenders reason to obey the law, it offers them the wrong kind of reason: instead of addressing them as responsible moral agents, in terms of the moral reasons which justify the law's demands on them, it addresses them as merely self-interested beings, in the coercive language of threat; deterrence treats ‘a man like a dog instead of with the freedom and respect due to him as a man’ (Hegel 1821: 246. For these objections see Lewis 1953; H Morris 1968; von Hirsch 1993: 9-14; von Hirsch & Ashworth 1998, chs. 1, 3).

Such objections leave many people unpersuaded -- in particular the Hegelian objection to a side-constrained system of deterrent punishments that punishes only the guilty. One response is to argue that those who voluntarily break the law thereby forfeit at least some of the rights that citizens can normally claim: their wrongdoing legitimises kinds of treatment (reformative or incapacitative treatment, for instance) that would normally be wrong as right-violating (see Goldman 1982; C Morris 1991). Another response is to argue that a side-constrained system of deterrent punishments can be shown to be consistent with a proper respect for those who are punished, or threatened with punishment, by portraying it as a

species of societal (self-) defence (for versions of this kind of argument see Alexander 1980; Quinn 1985; Farrell 1985, 1995; Montague 1995); or by pointing out that it offers self-interested agents who are deaf to the law's moral appeal prudential reasons which they can grasp and see as relevant (Baker 1992). (On these arguments see Duff 2000, chs. 1.3, 3.1-3.) Even those who find the Hegelian objection to deterrent punishment persuasive can recognise such an account of punishment as a system of side-constrained deterrence offering those who are unmoved by the moral reasons for refraining from crime prudential reason to do so as the most plausible form that a consequentialist (but not purely consequentialist) theory of legal punishment can take.

However, we have already noted that a side-constrained consequentialism might need to appeal to a negative retributivist notion of desert to ground its side-constraints; we must now examine some of the ways in which that notion of penal desert has been used to ground, not merely negative side-constraints on the pursuit of some consequentialist end, but a positive justification of punishment.

5. ‘Positive’ Retributivism and the Meaning of Desert

‘Positive’ retributivism holds not merely that we must not punish the innocent (or punish the guilty more than they deserve), but that we should punish the guilty (to the extent that they deserve): penal desert constitutes not just a necessary, but a sufficient reason for punishment, or at least a strong positive reason for it. A striking feature of penal theorising during the last three decades of the twentieth century was a revival of positive retributivism -- of the idea that the positive justification of punishment is to be found in its intrinsic character as a deserved response to crime (see H. Morris 1968; N. Morris 1974; Murphy 1973; von Hirsch 1976).

Retributivism comes in very different forms (Cottingham 1979). All can be understood, however, as attempting to answer the two central questions faced by any retributivist theory of punishment. First, what is the justificatory relationship between crime and punishment that the idea of desert is supposed to capture: why do the guilty ‘deserve to suffer’ (see L. Davis 1972) -- and what do they deserve to suffer (see Ardal 1984; Honderich 1984, ch. 2)? Second, even if they deserve to suffer, why should it be for the state to inflict that suffering on them through a system of criminal punishment (Murphy 1985; Husak 1992; Shafer-Landau 1996)?

One retributivist answer to these questions which was popular for a time was that crime involves taking an unfair advantage over the law-abiding, and that punishment removes that unfair advantage. The criminal law benefits all citizens by protecting them from certain kinds of harm: but this benefit depends upon citizens accepting the burden of self-restraint involved in obeying the law. The criminal takes the benefit of the self-restraint of others, but refuses to accept that burden herself: she has gained an unfair advantage, which punishment removes by imposing some additional burden on her. (See H. Morris 1968; Murphy 1973; Sadurski 1985; Sher 1987, ch. 5; Adler 1992, chs. 5-8; Dagger 1993: for criticism, see Burgh 1982; Falls 1987; Dolinko 1991; Anderson 1997).

This kind of account does indeed answer the two questions noted above. What the criminal deserves to suffer is the loss of her unfair advantage, and she deserves that because it is unfair that she should get away with taking the benefits of the law without accepting the burdens on which those benefits depend; it is the state's job to inflict this suffering on her, because it is the author or guarantor of the criminal law. However, such accounts have internal difficulties: for instance, how are we to determine how great was the unfair advantage gained by a crime; how far are such measurements of unfair advantage likely to correlate with our judgements of the seriousness of crimes? (For a detailed defence of the 'unfair advantage' theory as a theory of sentencing, see M. Davis 1992, 1996; for criticism see Scheid 1990, 1995; von Hirsch 1990.) Furthermore, they seem to misrepresent what it is about crime that makes it deserving of punishment: what makes murder, or rape, or theft, or assault a criminal wrong, deserving of punishment, is surely the wrongful harm that it does to the individual victim -- not (as on this kind of account) the supposed unfair advantage that the criminal takes over all those who obey the law.

A different retributivist account appeals not to the abstract notion of unfair advantage, but to our (normal, appropriate) emotional responses to crime: to, for instance, the resentment of 'retributive hatred', involving a desire to make the wrongdoer suffer, that crime may arouse (see Murphy & Hampton 1988, chs. 1, 3); or to the guilt, involving the judgement that I ought to be punished, that my own wrongdoing would arouse in me (see Moore 1997, ch. 4). Such accounts try to answer the first of the two questions noted above: crime deserves punishment in the sense that it makes appropriate certain emotions (resentment, guilt) which are satisfied by or expressed in punishment. However, they do not yet show why it should be the state's task to satisfy or provide formal expression for such emotions (but see Stephen 1873: 152); and their answers to the first question are also problematic. Criminal wrongdoing should, we can agree, provoke certain kinds of emotion, such as self-directed guilt and other-directed indignation; and such emotions might typically involve a desire to make those at whom they are directed suffer. But just as we can agree that anger is an appropriate response to wrongs done to me, whilst also arguing that we should resist the desire to hit back which anger often, even typically, involves (see Horder 1992:194-7): so we could argue that we should resist the desire for suffering that guilt and resentment typically involve. At the least we need to know more than we are told by these accounts about just what wrongdoers deserve to suffer, and why the infliction of suffering should be an appropriate way to express such proper emotions. (For critical discussions of Murphy, see Murphy & Hampton 1988, ch. 2; Duff 1996: 29-31; Murphy 1999. On Moore, see Dolinko 1991: 555-9; Knowles 1993; Murphy 1999.)

A third kind of account seeks the meaning and justification of punishment as a deserved response to crime in its expressive or communicative character. (On the expressive dimension of punishment, see generally Feinberg 1970, Primoratz 1989: for critical discussion see Hart 1963: 60-69; Skillen 1980; M. Davis 1996: 169-81.) Consequentialists can of course portray punishment as useful partly in virtue of its expressive character (see Lacey 1988; Braithwaite & Pettit 1990): but a portrayal of punishment as a mode of moral communication has been central to some recent versions of retributivism.

6. Punishment as Communication

The central meaning and purpose of punishment, on such accounts, is to communicate to offenders the

censure or condemnation that they deserve for their crimes. Once we recognise, as we should, that punishment can serve this communicative purpose, we can see how such accounts begin to answer the two questions that retributivists face. First, there is an obviously intelligible justificatory relationship between wrongdoing and censure -- as a response which is intended to bring pain (the pain of condemnation by one's fellows) to an offender for his offence: whatever puzzles there might be about other attempts to explain the idea of penal desert, the idea that wrongdoers deserve to suffer censure is surely unpuzzling. Second, it is appropriate for the state to ensure that such censure is formally administered through the criminal justice system: for crimes are public wrongs, breaches of the political community's authoritative code; as such, they merit public censure by the community. Furthermore, whilst internal to censure is the intention, or hope, that the person censured will accept the censure as justified and will thus be motivated to avoid crime in future, this kind of account can avoid the charge (as brought against consequentialist theories) that it seeks to coerce or manipulate offenders into obeying the law. For censure addresses, and respects, the person censured as a rational and responsible agent: it constitutes an appropriate, deserved response to the wrong that she did, and seeks to bring her to modify her future conduct only by reminding her of the good moral reasons that she has for refraining from crime (see von Hirsch 1993, ch.2; Duff 2000, chs. 1.4.4, 3.2).

However, an obvious and crucial question faces any such justification of punishment as a communicative enterprise. Censure can be communicated through a formal conviction in a criminal court; or it could be communicated by some further formal denunciation issued by a judge or some other representative of the legal community, or by a system of purely symbolic punishments which were painful only in virtue of their censorial meaning. It can, of course, also be communicated by ‘hard treatment’ punishments of the kinds imposed by our courts -- by imprisonment, by compulsory community service, by fines and the like, which are painful or burdensome independently of their censorial meaning (on ‘hard treatment’, see Feinberg 1970): but why should we choose such methods of communication, rather than methods that do not involve hard treatment (see Christie 1981: 98-105)? Is it because they will make the communication more effective (see Falls 1987; Primoratz 1989; Kleinig 1991)? But why is it so important to make the communication effective -- and is there not a serious danger that the hard treatment will conceal, rather than highlight, the moral censure it should communicate (see Mathiesen 1990: 58-73)?

One kind of answer to this question brings consequentialism and deterrence back into the picture: we should communicate censure through penal hard treatment because this will give those who are insufficiently impressed by the moral appeal of censure prudential reason to refrain from crime; because, that is, the prospect of such punishment might deter those who are not susceptible to moral persuasion. (See Lipkin 1988, Baker 1992; and for a sophisticated revision of this idea, which makes deterrence firmly secondary to censure, see von Hirsch 1993, ch. 2; Narayan 1993: for critical discussion see Bottoms 1998; Duff 2000, ch. 3.3.) This kind of account differs from the side-constrained consequentialist accounts discussed earlier, since the (retributivist) imposition of deserved censure is now part of the positive justifying aim of punishment; and it can claim, in response to the Hegelian objection to deterrence, that it does not address potential offenders merely ‘like dogs’, since the laws initial appeal to the citizen is in the appropriate moral terms: the prudential, coercive reasons constituted by penal hard treatment as deterrence are relevant only to those who are deaf, or at least insufficiently attentive, to the law's moral appeal. It is still true, however, that on this account the law, in speaking to those who are not

persuaded by its moral appeal, is to abandon the attempt at moral communication in favour of the brute language of threats; and, for those who take seriously the Kantian demand that the state and its law should address its citizens as responsible moral agents, this slide into deterrence is still morally problematic.

A different answer to the ‘Why hard treatment?’ question explains penal hard treatment as an essential aspect of the enterprise of moral communication itself. Punishment, on this view, should aim not merely to communicate censure to the offender, but to persuade the offender to recognise and repent the wrong he has done, and so to recognise the need to reform himself and his future conduct, and to make apologetic reparation to those whom he wronged. His punishment then constitutes a kind of secular penance that he is required to undergo for his crime: its hard treatment aspects, the burden it imposes on him, should serve both to assist the process of repentance and reform, by focusing his attention on his crime and its implications, and as a way of making the apologetic reparation that he owes. (See Duff 2000. This kind of account has some relation to accounts that portray punishment as a kind of moral education: see H. Morris 1981; Hampton 1984; for criticism see Deigh 1984; Shafer-Landau 1991). This account faces serious objections (see Bickenbach 1988; Ten 1990; von Hirsch 1999; Bagaric & Amarasekara 2000): in particular that it cannot show penal hard treatment to be a necessary aspect of a communicative enterprise which is still to respect offenders as responsible and rational agents who must be left free to remain unpersuaded; that apologetic reparation must be voluntary if it is to be of any real value; and that a liberal state should not take this kind of intrusive interest in its citizens' moral characters. We cannot discuss these objections here, but should turn to a currently prominent strand in abolitionist thought, with which this communicative account of punishment can be usefully compared.

7. ‘Restorative Justice’

The ‘restorative justice’ movement has been growing in strength: although there are different and conflicting conceptions of what ‘restorative justice’ means or involves, the central theme is that what crime makes necessary is a process of reparation or restoration between offender, victim and other interested parties; and that this is achieved not through a criminal process of trial and punishment, but through mediation or reconciliation programmes that bring together the victim, offender and other interested parties to discuss what was done and how to deal with it (see generally Matthews 1988; Daly & Immarigeon 1998; von Hirsch & Ashworth 1998, ch. 7; Braithwaite 1999).

Now advocates of restorative justice often contrast it with ‘retributive’ justice, and argue that we should look for restoration rather than retribution or punishment. But it could be argued that this is a mistake. For when we ask what it is that requires ‘restoration’ or repair, the answer must refer not only to whatever material harm was caused by the crime, but to the wrong that was done: that was what fractured the relationship between offender and victim (and the broader community), and that is what must be recognised and ‘repaired’ or made up for if a genuine reconciliation is to be achieved. A restorative process that is to be appropriate to crime must therefore be one that seeks an adequate recognition, by the offender and by others, of the wrong done -- a recognition that must for the offender, if genuine, be repentant; and that seeks an appropriate apologetic reparation for that wrong from the offender. But those are also the aims of punishment as a species of secular penance, as sketched above.

This argument does not, of course, support that account of punishment against its critics. What it might suggest, however, is that whilst we can learn much from the restorative justice movement, especially about the role that processes of mediation and reparation can play in our responses to crime, its aim should not be the abolition or replacement of punishment: ‘restoration’ is better understood, in this context, as the proper aim of punishment, not as an alternative to it (see further Duff 2000, ch. 3.4-6, but also Zedner 1994).

8. Further Issues

The previous sections sketched the central contemporary accounts of whether and how legal punishment can be justified -- and some of the objections and difficulties that they face. A number of further important questions face any theory of punishment, which can only be noted here.

First, there are questions about sentencing. Who should decide what kinds and what levels of sentence should be attached to different offences or kinds of offence: what should be the respective roles of legislatures, of sentencing councils or commissions, of appellate courts, of trial judges, of juries? By what criteria should such decisions be made: how far should they be guided by a retributivist principle of proportionality, requiring punishments to be ‘proportionate’ in their severity to the seriousness of the crime; how far by consequentialist considerations of efficient crime-prevention? What kinds of punishment should be available to sentencers, and how should they decide which mode of punishment is appropriate for the particular offence (considerations of the meaning of different modes of punishment should be central to this question)? (On sentencing see generally Robinson 1987; Morris & Tonry 1990; von Hirsch 1993; Tonry 1996; von Hirsch & Ashworth 1998)

Second, there are questions about the relation between theory and practice -- between the ideal, as portrayed by a normative theory of punishment, and the actualities of existing penal practice. Suppose we have come to believe, as a matter of normative theory, that a system of legal punishment could in principle be justified -- that the abolitionist challenge can be met. It is, to put it mildly, unlikely that our normative theory of justified punishment will justify our existing penal institutions and practices: it is far more likely that such a theory will show our existing practices to be radically imperfect -- that legal punishment as it is now imposed is far from meaning or achieving what it should mean or achieve if it is to be adequately justified. If our normative theorising is to be anything more than an empty intellectual exercise, if it is to engage with actual practice, we then face the question of what we can or should do about our current practices. The obvious answer is that we should strive so to reform them that they can be in practice justified, and that answer is certainly available to consequentialists, on the plausible assumption that maintaining our present practices, whilst also seeking their reform, is likely to do more good or less harm than abandoning them. But for retributivists who insist that punishment is justified only if it is just, and for communicative theorists who insist that punishment is just and justified only if it communicates an appropriate censure to those who deserve it, the matter is harder: for to maintain our present practices, even while seeking their radical reform, will be to maintain practices which perpetrate serious injustice (see Murphy 1973; Duff 2000, ch. 5).

Third, the relation between the ideal and the actual is especially problematic in the context of punishment partly because it involves the preconditions of just punishment. That is to say, what makes an actual system of punishment unjust(ified) might be not its own operations as such (what punishment is or achieves within that system), but the absence of certain political, legal and moral conditions on which the whole system depends for its legitimacy (see Duff 2000, ch. 5.2). For instance, a just system of criminal law must convict and punish only those who are responsible, in the sense of being answerable for their crimes: only those who have the capacities necessary to answer for their actions, who are bound by this criminal law, and who are answerable to the political community whose law it is and whose courts call them to answer. There is much work to be done in spelling out such preconditions of just punishment: but it is at least arguable that they are far from satisfied for many of those who are convicted and punished by our own systems of criminal justice. To the extent that they are not satisfied, however, those systems lack legitimacy, and the punishments they inflict are unjustified. This conclusion should not surprise us: but it challenges any comfortable assumption that we can support and rely on our existing systems of criminal justice with a clear conscience.

Brentano's Theory of Judgement

One of Brentano's foremost aims in philosophy was to provide a new foundation for epistemology and logic as two closely related disciplines. He tried to achieve this by a systematic analysis of the mental phenomena involved in attaining knowledge and in drawing inferences. For Brentano knowledge is reached by judgements that are directly or indirectly evident, and logical inferences can contribute to our knowledge because they can make a judgement indirectly evident for us. Hence both epistemology and logic rely on a conception of judgements, how they differ from other mental phenomena, and how they are related to each other.

Brentano's view of the nature of judgement differs significantly from other views that can be found in Aristotle, Kant, or Frege. In contrast to Aristotle, Brentano emphasizes the importance of existential judgements with only one term, and claims that predicative judgements are a special case of existential ones. In contrast to Kant, he emphasizes the difference between presentations and judgements, rejecting their unification in the single category ‘thinking’. In contrast to Frege, he holds that judgements do not require the existence of complete thoughts or propositions which have to be grasped before a judgement can be made. It is the mental act of judging, not its object or content, which is the bearer of truth-values. In view of these differences Brentano's theory of judgement has been called *existential* (non-predicative), *idiogenetic* (non-reductionist), and *reistic* (non-propositional).

Today Brentano's theory does not have many adherents. The now dominant view is that propositions or sentences are the objects of belief, and that judgements occur when beliefs are acquired, manifested, or changed. Logical inferences are then defined as relations between propositions or sentences, abstracting from the mental attitudes that go along with them. Although this anti-psychological approach is widely accepted today, there is still an open question concerning the order of explanation here: Are beliefs and judgements true because they are directed at true propositions, or should we say that propositions (and sentences) are true because they express true beliefs and judgements? Once this question is raised, Brentano's theory of judgement remains an interesting alternative to the current mainstream in logic and epistemology.

The Nature of Judgement

The main elements of Brentano's theory of judgement can be found in chapter 7 and appendix IX of his *Psychology from an Empirical Standpoint* (1874; the appendix was added in the second edition 1911). A more elaborate exposition of his theory is contained in the logic lectures which Brentano held at the University of Wuerzburg (1869-71) and at the University of Vienna (1875-1889). Unfortunately Brentano never realized his plan -- announced in the second edition of the *Psychology* (Vol. II, p.77n/p.230n) -- to publish his elementary logic as a whole. Up to now only a small selection of his lecture notes, mixed with excerpts from other writings by Brentano and his pupil Franz Hillebrand, has been published in *Die Lehre vom richtigen Urteil* (1956).

Brentano's leading question was a psychological one: What happens in our minds when we make a judgement? Introspectively it is an act quite similar to making a decision, although its behavioral effects are different. Suppose you are uncertain what to think about the existence of extraterrestrial life. Some data suggest that life exists only on earth, others suggest that there may be intelligent beings somewhere else in the universe. Eventually you may become convinced one way or the other, and you either accept or reject the existence of extraterrestrial life. That is when you *judge*.

This example illustrates three crucial claims that Brentano makes:

> (1) Judgements require that something (some object) is given in presentation, but not that something is predicated of it.
>
> (2) Judgements are either positive or negative, depending on whether the presented object is accepted as existing, or rejected as fictitious or non-existing.
>
> (3) Judgements are best expressed in sentences of the form ‘A exists’ or ‘A does not exist’, where the term ‘A’ denotes the presented object which is also the object of the judgement, and the rest of the sentence indicates its quality.

These three claims form the core of Brentano's theory of judgement: The *foundational thesis* (1) concerns the relation between judgement and predication, the *polarity thesis* (2) determines the place of negation in judgements, and the *existential thesis* (3) determines a canonical form in which all judgements can be expressed. Of course, these claims must be seen in the context of Brentano's overall theory of mental phenomena, in particular in the context of his account of intentionality. This background cannot be

discussed here, but it is worth mentioning that the term ‘object of judgement’, as it is used here, always refers to an entity which is distinct from the judgement itself and not contained in it. It is also assumed here that judgements have a content or subject matter, which is not separable from the act itself, and which Brentano originally called the ‘immanent objectivity of a mental phenomenon’. The content of a judgement must not be conceived as a propositional entity, however, since Brentano explicitly denied that judgements have such entities as their contents. (Complex entities which are not propositional and which are just as ephemeral as the content of a judgement can already be found in Aristotle; see G. B. Matthews, 1982.)

All three of Brentano's claims above were already highly controversial among his immediate pupils. We find for instance in Husserl's fifth Logical Investigation an account of judgements which deviates from Brentano in all three respects. According to Husserl judgements are intentional acts with a propositional content directed at proposition-like entities which he calls *Sachverhalte*. Why Husserl deviated from his teacher in such a radical way, and whether he did so for good reasons, are questions still in discussion today. (See for instance Mulligan 1988).

The Foundational Thesis and the Judgement/Predication Distinction

The claim that judgements are based on presentations is a commonplace in philosophy, but it is a matter of controversy how this relationship should exactly be spelled out. Traditional logic suggests that two presentations must be involved in every judgement, since a judgement is made when something is attributed or denied of something else. Therefore the sentences that are traditionally used for expressing judgements have the subject-predicate form ‘S is P’ and ‘S is not P’.

Brentano rejects this traditional view by pointing out that judgements may arise also from a single presentation. When someone judges that extraterrestrials exist, he does not connect the notion of extraterrestrial life with the notion of existence. He merely thinks of such beings and accepts their existence, i.e. he has a presentation of such beings and accepts it as a presentation of something existing. Existential judgements are therefore not to be expressed in the subject-predicate form ‘S is P’, but in the simple form ‘A exists’, when ‘A’ is a singular term, and ‘A's exist’ or ‘Some A exist’, when ‘A’ is a general term. (Brentano mentions in a footnote that Aristotle himself may have acknowledged simple judgements of this form. *Psycholog*y Vol. II, p.54n/p.211n).

Existential judgements show that predication is not *necessary* for forming a judgement, but neither is it sufficient according to Brentano. Many philosophers have assumed that a predicative judgement is nothing more than ‘the putting together of two ideas’ -- in the case of ‘S is P’ -- or ‘the separating of two ideas’ -- in the case of ‘S is not P’. This view is sometimes called the ‘combinatorial theory of judgement’, and Brentano was not the first to point out the deficiences of this view. He refers to John Stuart Mill who already denied that judgements arise from a habit of associating or dissociating ideas. What Brentano adds to Mill's criticism is a precise diagnosis of the mistake: the combinatorial theory

tries to locate the characteristic feature of a judgement in its *content* instead of locating it in its *quality*. When we combine a subject- and a predicate-term we just form a more complex idea which is again the content of a presentation. What is still missing is the qualitative moment of acceptance or rejection (see *Psychology*, Vol II, p.63/p.221).

Thus Brentano's theory draws a sharp line between judgement and predication in recognizing judgements with a non-predicational content and in taking subjectless sentences at face value. Sentences like ‘It is raining’ or ‘There is no water on the moon’ need not be paraphrased into subject-predicate form along the lines of ‘The weather is rainy’ or ‘The moon is lacking water’. They directly express a judgement by specifying an object which is given in presentation (rain, water on the moon) and by indicating whether this object is accepted or rejected. (This advantage of Brentano's theory was especially exploited by Marty 1884-1895).

Things get more complicated, however, when Brentano later (in appendix IX of the second edition of the *Psychology*) introduces so-called ‘double judgements’. In making a double judgement one first accepts the existence of something, and then adds to this first judgement a second one to the effect that the object, whose existence one already has accepted, either has or lacks some property. According to this refined view, a predication is made not by combining two ideas or presentations, but by combining two judgements.

The introduction of double judgements leaves the analysis of existential judgements intact, since in judging that S exists we do not first accept S as existing and then attribute existence or non-existence to it. However, one can now predicate P of S in two different ways: either by first forming the complex presentation of an object S which is P and then accepting this object, or by first accepting the existence of S and then attributing P to it, thus making the double judgement that S is P. In this latter case too, the attribution of P involves two steps: first the predicate P is connected merely in presentation with object S whose existence has been accepted, and then the object S is accepted once more, but this time together with P as one of its properties. That predication and judgement remain distinct acts also in the case of double judgements can be seen from the following fact: When we imagine a person (perhaps oneself) who is double-judging that S is P, we can disagree only with the second part of her judgement, and still form the complex presentation of an S which is P. And conversely, we can form the complex presentation of an S which is P and yet agree with the double judgement that S is not P. (See *Psychologie*, Vol. II, p.164/p.295. This point is further elaborated in Terrell 1976).

In its final form Brentano's account of the relation between judgement and predication turns out to be less straightforward than the standard Fregean account with its simple distinction between ‘grasping a proposition’ and ‘judging it to be true’. At no point did Brentano, however, lose sight of the claim that predication is not essentially connected with judging.

The Polarity Thesis and the Judgement/Negation Distinction

According to Brentano's second thesis, judgements are always positive or negative. In this respect they are like preferences and emotional attitudes which are for or against something. (Brentano holds the controversial view that feelings and acts of will belong to the same category and that they all involve such a polarity.) Presentations, on the other hand, are neither positive nor negative. They simply present an object to the mind without taking a stance towards it. This happens when we simply see or hear something, or when we imagine something in our phantasy. As long as no judgement is made (and no emotional evaluation and no preference is involved), there is nothing positive or negative about an act of presentation.

This essential difference tends to be overlooked when one uses the single category of ‘thinking’ for both judgements and presentations, as does the Kantian tradition. According to Brentano presentations and judgements are as different from each other as they are different from feelings and acts of will. Their difference is not just external -- having to do with the way in which they influence our actions -- it is an internal difference lying in the distinctive quality of judgements. Therefore, if one acknowledges that feelings or acts of will form a separate category besides the category of ‘thinking’, one should accept for the same reason that judgements and presentations form distinct categories as well.

With his polarity thesis Brentano not only dismisses the Kantian tradition, he also rejects a view that Frege made popular, namely that there are no negative judgements. When we deny the existence of something, e.g. the existence of extraterrestrial life, we still accept something as true, Frege would say, namely the negative thought that there are no extraterrestrials. Negation enters the formation of *thoughts*, it does not divide *judgements* into positive and negative.

Frege's elimination of negative judgements rests on the assumption that thoughts (or judgement-contents) can be true or false independently of being accepted or rejected, and therefore can also be negated. Brentano does not explicitly discuss this view, but his objection to it seems clear: The polarity between truth and falsity must be grounded in our ability to form opposite judgements. We first have to realize that from two opposing judgements with respect to the same subject matter, one will be true and the other one false. Only then can we understand what it means for a sentence, (a judgement content, a proposition, a thought, or whatever), to be true or false. (These issues are further discussed in Reinach 1911).

Brentano's treatment of negation has important further consequences. First, if the contrast between truth and falsity is explained along these lines, then the contrast between positive and negative concepts must also be explained at the level of judgements, not at the level of presentations. In his later writings Brentano took up this challenge when he tried to show that only positively conceived ‘things’ are properly regarded as objects of presentations. This became his ontological doctrine called *reism*. (On this issue see Körner 1978).

Secondly, if negation is completely eliminated from the level of presentaions, the analysis of categorial judgements has to be revised accordingly. Initially, Brentano paraphrased these judgements in existential form as follows:

I: Some S are P	There is an S which is P
E: No S is P	There is no S which is P
O: Some S are not P	There is an S which is a non-P
A: All S are P	There is no S which is a non-P

The negation in E-judgements poses no problem: it properly indicates that a negative judgement is made. The negative concept ‘non-P’ used in the paraphrases of O- and A-judgements is more problematic, however. Here a negation enters at the level of presentations, not at the level of judgement as the polarity thesis requires.

A more complicated analysis is required to get around this difficulty. In the case of O-judgements the introduction of double judgements will help. It then turns out that an O-judgement does not consist in predicating non-P of S, but in first accepting S and then making a negative judgement to the effect that S is not P, i.e. a judgement that denies the application of P to S. This still leaves the A-judgements as a problem case. At this point Brentano again invokes a higher-level presentation, namely the presentation of someone whose judgements are evaluated as right or wrong. With these additional tools at hand, Brentano arrives at the following analysis of the four categorical judgements (see *Psychology*, Vol. II, 164-169/pp.295-298):

I: Some S are P	There is an S and that S is P
E: No S is P	There is no one who correctly judges ‘Some S is P’
O: Some S are not P	There is an S and that S is not P
A: All S are P	There is no one who correctly judges ‘Some S are not P’

All negations here indicate that a negative *judgement* is made. This vindicates the claim that the polarity between positive and negative judgements is *basic* and provides the distinguishing mark that separates judgements from presentations. Brentano admits, however, that for practical reasons it may be convenient to use negative concepts, e.g. for simplifying inferences. When one does so, one should keep in mind however that these concepts do not properly pick out objects of presentation. Along these lines one could also justify the use of propositional clauses and thereby avoid all the complications of the existential analysis; but Brentano does not seem to have considered this more radical simplification (see *Psychology*, Vol. II, p.169/p.299).

The Existential Thesis

Brentano's third thesis says that all simple judgements (that involve only a simple act of judging) can be expressed in sentences of the form ‘A exists’ or ‘A does not exist’ (or ‘A's exist’ and ‘A's do not exist’ respectively). This thesis marks the contrast to all propositional theories of judgement. Propositional

theories assume that a complete sentence (or a that-clause) is needed for expressing the content of a judgement. That a proposition (or sentence) is actually accepted, i.e. that a judgement is made, must therefore be indicated by an additional sign -- like Frege's judgement-stroke -- or it remains implicit in the assertive use of a declarative sentence.

On Brentano's theory, by contrast, only a simple or complex *term* is needed to express the content of a judgement, and hence a complete sentence can express both the *content* and the *quality* of a judgement. In making this claim, Brentano relies on the distinction between categorematic and syncategorematic expressions, i.e. between terms that purport to denote entities, and expressions like ‘is’, ‘and’, ‘or’, etc. that do not. The former specify the content of a judgement, whereas the latter are used for specifying its quality. This distinction also applies to sentences of the form ‘A exists’. Here the ‘exists’ does not purport to denote anything -- the property of existence -- rather it indicates which judgement is made: A positive judgement in present tense in the case of ‘A exists (now)’, a negative judgement in the present tense in the case of ‘A does not exist now’, a positive judgement in the past tense in the case of ‘A existed’, a negative apodictic judgement in the case of ‘A does necessarily not exist’, etc. (I consider here throughout only the most basic distinction between positive and negative cases.)

Brentano also introduces two special signs to separate those sentence parts that specify the content of a judgement from those that specify its quality. He uses the sign ‘+A’ to express the positive judgement that A exists, and the sign ‘−A’ to express the negative judgement that A does not exist. These signs remind one of Frege's judgement stroke, but the theory behind them is quite different. Two important differences should be noted here:

Firstly, ‘+A’ is not be read as ‘it is accepted that A exists’. This would suggest that the sign ‘+’ functions as the operator ‘it is accepted that’, and that the term ‘exists’ expresses part of the content of the judgement. But the whole point of Brentano's theory is that the term ‘exists’ is syncategorematic and merely expresses the *quality* of the judgement. ‘A’ alone must therefore express the whole (non-propositional) content. This also tells against a suggestion made by Arthur Prior, namely to read ‘A exists’ as ‘Something is A’. It is not enough to treat ‘existence’ as a second-level predicate to avoid the misinterpretation that it contributes to the content of the judgement (see Prior 1976, p.115).

Secondly, ‘−A’ should not to be read as ‘the existence of A is rejected’. This would suggest that there is a difference between ‘the existence of A is rejected’ and ‘the non-existence of A is accepted’, and equally between ‘A is rejected as existing’ and ‘A is accepted as non-existing’. Brentano's theory leaves no room for such distinctions. Otherwise it would reduce to the (non-controversial) claim that all categorial judgements are expressible in the form of existential propositions. Brentano's much stronger claim is however that no propositions at all are accepted in such judgements, not even existential ones.

What, then, is the best way to read the formulas ‘+A’ and ‘−A’? There is no better way than reading them as ‘A exists/does not exist’ or as ‘A is accepted/rejected’. Whatever term we use for the symbols ‘+’ and ‘−’, they will have no specific meaning beyond their function of indicating the quality of the judgement expressed.

Having noted these differences between Brentano's and Frege's symbolism, one may wonder whether Brentano really has a consistent theory here.

One problematic fact is that it is unclear how to interpret the formulas ‘+A’ and ‘−A’ when they are not used, but merely mentioned. When such a formula is quoted, the expression ‘A’ is still meaningful and expresses the content of a judgement, but the signs ‘+’ and ‘−’ become completely idle. This, of course, is also true of Frege's judgement stroke, which loses its function when it is not used to make an assertion.

However, there seems to be further difficulty that is peculiar only to Brentano's symbols. Whereas Frege's judgement-stroke is added to complete sentences, Brentano's symbols are *parts* of complete sentences. But every complete sentence can be used without expressing a judgement, for instance as the antecedent or consequent of a conditional. There is no obstacle in forming the complex judgement ‘If A exists, then B does not exist’, and yet we cannot symbolize it as ‘If +A, then −B’. Apparently, then, the term ‘exist’ is not (or not merely) an indicator of the judgement-quality, as Brentano would have it. (This objection was raised in Geach 1965.)

In dealing with this objection one might appeal to Brentano's own treatment of conditional (or hypothetical) judgements. He reduces them to *single* existential judgements with a complex object. Thus, a judgement of the form ‘If A exists, then B does not exist’ gets analysed as ‘An A together with a B does not exist’, where ‘A together with B’ denotes the complex object which is rejected (see *Psychology* Vol. II, p.170/p.299; see also *Lehre* p.123).

But there is more to Geach's objection. It shows that on Brentano's theory the term ‘exists’, like the copula ‘is’, can be used in two different ways. It can either be used to *express* a judgement or to *talk about* a judgement made by someone (possibly by oneself). We have already seen how Brentano uses this distinction for separating judgement and presentation, and for analysing A-judgements without invoking negative concepts. He also needs to make use of this distinction when it comes to conditional judgements. The judgement ‘If A exists, then B does not exist’ might then be analysed as ‘It is impossible correctly both to accept A and to reject B’, which can be expressed in existential form as ‘Someone who can correctly accept A and reject B does not exist’. (This analysis is suggested in Chisholm 1982, p.36).

In this way Brentano's theory of judgement may be applicable to a wider range of complex judgements (see Pasquarella 1987). Even if these extensions are rejected as unnecessarily complicated however, Brentano's existential analysis offers a viable alternative to the propositional theory at least for some basic kinds of judgements, like the ones used in syllogistic. This may not be very significant from the point of view of modern logic, which does not distinguish between basic and non-basic judgements in this way, but it may have a considerable *ontological* significance. Brentano's theory shows how a commitment to propositional entities can be avoided at least within certain limits. Entities like ‘propositions’, ‘states of affairs’, ‘facts’, ‘Meinongian objectives’, etc. might therefore be introduced only for convenience, but they need not be taken ontologically seriously. Any stronger commitment to such entities remains therefore dubious, and it is for this reason that Brentano came to reject the

correspondence theory of truth. Judgements are true, according to his existential thesis, because certain entities *exist* (or do not *exist*), not because certain entities ‘correspond’ to our judgements. (Advocates of a correspondence theory have criticized Brentano precisely for this reason. See Schlick 1925, pp.60ff and 176ff).

The Reform of Logic

In the second half of the 19th century logic freed itself from the constraints of the Aristotelian tradition. This move is often linked with the demise of ‘psychologism’, the view that logic needs to be based on psychology. Mathematical logicians like Bolzano and Frege established modern logic as a strictly non-psychological, ‘objective’ discipline. From this point of view Brentano appears as one of the last advocates of the ‘old logic’, and his theory as a final attempt at providing a psychological foundation for logic.

It is true that Brentano rejected the idea of a ‘mathematical logic’ as he found it in the writings of George Boole (see *Psychology*, Appendix X). Nevertheless, as we have noticed, there are important points of convergence between Brentano's and Frege's views (of which neither of them seems to have been aware): (1) judgement is distinct from predication, (2) existence is not a first-level predicate, (3) logical analysis must penetrate the linguistic expressions which often disguise the form of our judgements. But this is not all. There is even more agreement between Brentano and modern logic, however, when one compares them with the old syllogistic logic.

This further convergence becomes visible when one considers Brentano's criticism of the traditional *square of opposition*. This square is made up of the four categorial judgements A (‘All S are P’), E (‘No S are P’), I (‘Some S are P’), and O (‘Some S are not P’), among which the following relations have been claimed to hold:

(i) A contradicts O, and vice versa.

(ii) E contradicts I, and vice versa.

(iii) A and E can be false but not true together (= law of contrariety)

(iv) I and O can be true but not false together (= law of subcontrariety)

(v) A implies I (= subalternation)

(vi) E implies O (= subalternation)

(vii) I converts into ‘Some P are S’ (simple conversion)

(viii) E converts into ‘No P is S’ (simple conversion)

(ix) A converts into ‘All non-P are non-S’ (conversion by contraposition)

(x) O converts into ‘Some non-P are not non-S’ (conversion by contraposition)

Brentano rejects almost all of these claims. After translating the categorical judgements into existential form (leaving aside double-judgements for the moment), he reaches the following conclusions:

(i) and (ii) are the only logical relationships correctly identified by traditional logic.

(iii) to (vi) are mistaken: If S is an empty term, both A and E are true, and both I and O are false.

(vii) and (viii) are correct, but not because of a conversion of one judgement into another one, but only because *one* judgement is expressed in two ways.

(ix) and (x) are correct, but no contraposition is needed; only a simple conversion is used.

All these results emerge from one major shift in the underlying theory of judgements: Traditional logic takes A and I to be positive judgements, and E and O to be negative ones. According to Brentano all universal judgements (both A and E) are negative and therefore lack any existential import, whereas all particular judgements (both I and O) are positive and have such import. Once this ‘mistake’ is corrected, most of the traditional disputes about their logical relationships become obsolete. This is why Brentano said that his theory "leads to nothing less than a complete overthrow, and at the same time, a reconstruction of elementary logic. Everything then becomes simpler, clearer, and more exact" (*Psychology* Vol.II 77/230). (For a critical survey of Brentano's logic reform see Prior 1962, pp.166ff. and Simons 1987).

When we compare Brentano's results with the doctrines of modern logic, we see that they are in complete agreement concerning (i) - (vi). With respect to (vii) and (x) there is at least no major disagreement. It is still acceptable to say that the simple conversion of terms is only a change in the linguistic expression of a judgement, not in the judgement itself, and the same can be said about the conversion of an A-judgement. Here, too, no contraposition is needed, since in predicate logic an A-judgement can be either expressed as an implication or a negated conjunction.

In conclusion one may say that Brentano's psychological approach to logic did not prevent him from arriving at results very close to what modern logic teaches us. Perhaps, then, the major difference between Brentano and modern logic should not be seen in his psychologism, but rather in his focus on general terms. Frege changed this focus with his function/argument analysis of sentences, thereby replacing general terms with unsaturated expressions. This step is missing in Brentano's theory, and that is what sets it apart from the mainstream in contemporary logic and epistemology.

Feminist History of Philosophy

The past two decades have seen an explosion of feminist writing on the philosophical canon, a development that has clear parallels in other disciplines like literature and art history. Since most of the writing is, in one way or another, critical of the tradition, a natural question to ask is: Why does the history of philosophy have importance for feminist philosophers? This question assumes that the history of philosophy is of importance for feminists, an assumption that is warranted by the sheer volume of recent feminist writing on the canon. This entry explores the different ways that feminist philosophers are interacting with the Western philosophical tradition.

Feminist philosophers engaged in a project of re-reading and re-forming the philosophical canon have noticed two significant areas of concern. The first is the problem of historical exclusion. Feminist philosophers are faced with a tradition that believes that there are no women philosophers and, if there are any, they are unimportant. Of course, women are not entirely absent from the history of philosophy, and that brings us to the second challenge we face. Canonical philosophers have had plenty to say about women and what we are like. In general terms, we often find that philosophical norms like reason and objectivity are defined in contrast to matter, the irrational or whatever a given philosopher associates with women and the feminine. Our tradition tells us, either implicitly through images and metaphors, or explicitly in so many words, that philosophy itself, and its norms of reason and objectivity, exclude everything that is feminine or associated with women.

In response, feminist philosophers have criticized both the historical exclusion of women from the philosophical tradition, and the negative characterization of women or the feminine in it. Feminist historians of philosophy have argued that the historical record is incomplete because it omits women philosophers, and it is biased because it devalues any women philosophers it forgot to omit. In addition, feminist philosophers have argued that the philosophical tradition is conceptually flawed because of the way that its fundamental norms like reason and objectivity are gendered male.[1] By means of these criticisms, feminist philosophers are enlarging the philosophical canon and re-evaluating its norms, in order to include women in the philosophical "us".

The following entry contains 3 major sections. Section 1 ("Feminist Criticisms of the Canon as Misogynist") describes feminist readings of the philosophical canon that challenge its derogatory characterizations of women. These are of three kinds: (a) readings that record the explicit misogyny of great philosophers (like Aristotle's description of a female as a deformed male); (b) readings that argue for gendered interpretations of theoretical concepts (like matter and form in Aristotle); (c) synoptic interpretations of the canon (like the view that, historically, reason and objectivity are gendered male).

The third category of feminist criticisms of the canon diagnoses where philosophy as a whole went most deeply wrong, and, in doing so, it constructs a negative canon of philosophy. The negative canon exposes the ways in which the views of canonical philosophers throughout the history of philosophy are explicitly or implicitly misogynist or sexist. Section 2 ("Feminist Revisions of the History of Philosophy") discusses the response of feminist philosophy to the myths that there are no women philosophers and, in any case, no important ones. One response has been the retrieval of women philosophers for the historical record. A related development is the elevation to the canon of women philosophers like Mary Wollstonecraft, Hannah Arendt and Simone de Beauvoir. Section 3 ("Feminist Appropriation of Canonical Philosophers") examines the way that feminist philosophers have been engaged in rereading the canon looking for antecedents to feminist philosophy in the work of those philosophers (e.g. Hume) and those theories (e.g. Arisotle's virtue ethics) that are most congenial to current trends in feminism or which provide most fuel for feminist thought. This is to use the canon as other movements have done--as a resource, and as confirmation that a feminist perspective or problem is securely rooted in our philosophical culture.

---

1. Feminist Criticisms of the Canon as Misogynist

> Women are capable of education, but they are not made for activities which demand a universal faculty such as the more advanced sciences, philosophy and certain forms of artistic production. ... Women regulate their actions not by the demands of universality, but by arbitrary inclinations and opinions.
>
> (Hegel 1973: 263)

The idea that the gender of philosophers is important or even relevant to their work is a thought that runs counter to the self-image of philosophy. So, it is interesting to explore how and why feminist philosophers came to the realization that gender is a useful analytic category to apply to the history of philosophy. We can distinguish two aspects to this process although, in many cases, the two aspects

merge into a single project. The first stage of realizing the importance of gender consisted of the cataloguing of the explicit misogyny of most of the canon. The second stage consisted of probing the theories of canonical philosophers in order to uncover the gender bias lurking in their supposedly universal theories. The second stage, the discovery that a philosopher's supposedly universal and objective theories were gender specific, raised the further question of whether or not the theoretical gender bias was intrinsic to the theory or extrinsic to it. Let me illustrate these points with Aristotle.

1.1 Explicit Statements of Misogyny in Philosophical Texts

There is no doubt that Aristotle's texts are misogynist; he thought that women were inferior to men and he said so explicitly. For example, to cite Cynthia Freeland's catalogue: "Aristotle says that the courage of a man lies in commanding, a woman's lies in obeying; that "matter yearns for form, as the female for the male and the ugly for the beautiful;" that women have fewer teeth than men; that a female is an incomplete male or "as it were, a deformity": which contributes only matter and not form to the generation of offspring; that in general "a woman is perhaps an inferior being"; that female characters in a tragedy will be inappropriate if they are too brave or too clever"(Freeland 1994: 145-46). However dispiriting or annoying this litany is, and whatever problems it presents to a woman studying or teaching Aristotle, it can be argued that Aristotle simply held a mistaken view about women and their capacities (as did most Athenians of his time). But, if this is so, then Aristotle's theories, or most of them, are not tarnished by his statements about women, and we can ignore them, since they are false.

I have chosen Aristotle as my example, but similar feminist critiques are available chronicling the explicit misogyny of other canonical figures like Plato and Kant. Feminist criticisms of Plato's theories stress dialogues (like the *Timaeus* and *Laws*) that characterize women as inferior to men rather than the egalitarian *Republic*. Kant's writings, like Aristotle's, provide the ideal target for feminist criticism because they contain both overt statements of sexism and racism, and a theoretical framework that can be interpreted along gender lines.[2]

1.2 Gendered Interpretations of Philosophical Concepts

If we consider Aristotle's theory of hylomorphism we find a connection between form and being male, and matter and being female. That is, we find that matter and form are gendered notions in Aristotle (Witt 1998). By a gendered notion I mean a notion that is connected either overtly or covertly, either explicitly or metaphorically with gender or sexual difference.[3] Furthermore, matter and form are not equal partners in Aristotle's metaphysics; form is better than matter. And since hylomorphism is the conceptual framework that underlies most of Aristotelian theory from metaphysics and philosophy of mind to biology and literary theory, it looks as if his supposedly universal and objective theories are gendered, and it looks as if his negative charactization of women tarnishes his philosophical theories.

Are Aristotle's theories intrinsically gendered and sexist, so that gender cannot be removed without altering the theories themselves? Several feminist philosophers have developed this thesis. For example, in "Woman Is Not a Rational Animal", Lynda Lange argues that Aristotle's theory of sex difference is

implicated in every piece of Aristotle's metaphysical jargon, and she concludes that "it is not at all clear that it [Aristotle's theory of sex difference] can simply be cut away without any reflection on the status of the rest of the philosophy"(Harding and Hintikka 1983: 2). Elizabeth Spelman has argued that Aristotle's politicized metaphysics is reflected in his theory of soul, which, in turn, is used to justify the subordination of women in the Politics (Spelman 1983). And, finally, Susan Okin has argued that Aristotle's functionalist theory of form was devised by Aristotle in order to legitimate the political status quo in Athens, including slavery and the inequality of women (Okin 1979: ch. 4).

If these scholars are right, then Aristotle's theories are intrinsically biased against women, and it is unlikely that they can have any value for feminists beyond the project of learning about the ways in which the philosophical tradition has devalued women. Alternatively, I have argued that the suspect gender associations with Aristotelian matter and form are extrinsic tothese concepts, and therefore removable from Aristotle's theories without substantially altering them (Witt 1998). The argument that Aristotle's gender associations are not intrinsic to his concepts of matter (female) and form (male) turns on the incompatibility of the position that matter is intrinsically female, and form intrinsically male with the position that every composite substance is a unity of matter and form. If every composite substance is a complex of matter and form, then each would be a hermaphrodite, rather than a male or a female as is the case with animals. Moreoever,whatever plausibility gender associations with matter and form might have with regard to animals, is lost entirely when we consider artifacts, like shoes and beds. If intrinsic gender associations with matter and form are incompatible with Aristotle's theory of substance and extrinsic gender associations are compatible with that theory, then the principle of charity dictates that we opt for the consistent interpretation.

Sometimes, as in the case of Descartes, the feminist argument in favor of a gendered theory is subtle since, unlike Aristotle, he expresses both a personal and a theoretical committment to equality. Further, his theories are not stated using gendered notions. Yet, some feminists have argued that his theory of mind-body dualism, and his abstract characterization of reason resonate with gender implications-- on the assumption that women are emotional and bodily creatures (e.g. Scheman 1993; Bordo 1987; Lloyd 1993b, ch. 3).

1.3 Synoptic Interpretations of the Philosophical Canon

The philosophical canon can allow the luster some of its members to be tarnished by feminist criticism, just as it has weathered criticisms from analytic or continental perspectives. The most radical feminist critics, however, have urged that the canon's central philosophical norms and values, like reason and objectivity, are gendered notions. The synoptic approch considers the Western philosophical tradition as a whole, and argues that its core concepts are gendered male. But, if this is so, then the Western philosophical tradition as a whole, and the central concepts that we have inherited from it, requires critical scrutiny by feminists. Moreover, philosophy's self-image as universal and objective, rather than particular and biased, is mistaken.

Feminist synoptic interpretations of the canon take several forms. The first, exemplified by Genevieve

Lloyd's *Man of Reason*, argues that reason and objectivity in the history of philosophy are gendered male.[4] The way that reason and objectivity are gendered male varies as philosophical theory and historical period varies, but the fact that they are gendered is a constant. From Aristotle to Hume, from Plato to Sartre, reason is associated with maleness. Therefore, the notion of reason that we have inherited, whether we are empiricists or existentialists, requires critical scrutiny.

The second form of synoptic interpretation, exemplified by Susan Bordo's *The Flight to Objectivity*, argues that the modern period in philosophy, and, in particular, the philosophy of Descartes, is the source of our ideals of reason and objectivity that are gendered male. In other words, this story chronicles a turn in philosophy coincident with the rise of modern science, which generated ideals of reason and objectivity that are deeply antagonistic to women and feminism.[5] Cartesian rationalism and the norms of modern science mark a decisive break with a philosophical and cultural tradition that was more accommodating of female characteristics and powers.

It is important to note that Lloyd and Bordo differ not only with regard to the historical story they tell concerning the maleness of reason, but also with regard to the way they understand that maleness. For Lloyd, the maleness of reason is symbolic and metaphorical rather than cultural or psychological. Lloyd does not intend the maleness of reason to refer to either a socially constituted gender category or a psychological orientation shared by males. "This book is not a direct study of gender identity. It seeks rather to contribute to the understanding of how the male-female distinction operates as a symbol in traditional philosophical texts, and of its interactions with explicit philosophical views of reason".[6] In understanding the maleness of reason as symbolic rather than as psychological or social, Lloyd avoids making a theoretical committment to any particular psychology of sex differences or any particular account of the social formation of gender identity. What she gains in flexibility, however, she loses in content, since it is difficult to specify exactly what metaphorical maleness is, and how it is related to psychological or social maleness. Other feminists have attempted to develop an account of how male metaphors and symbols undermine philosophical arguments (Rooney 1991).

For Bordo, however, the maleness of Cartesian reason is given both a social meaning and a psychological content. First, the social meaning of maleness: "In the seventeenth century it [the feminine orientation toward the world] was decisively purged from the dominant intellectual culture, through the Cartesian ‘rebirthing’ and restructuring of knowledge and the world as masculine"(Bordo 1987: 100). This social meaning is paired with a psychological consequence: "The ‘great Cartesian anxiety,’ although manifestly expresssed in epistemological terms, discloses itself as anxiety over separation from the organic female universe"(Bordo 1987: 5). Cartesian ‘anxiety’ is separation anxiety from mother nature; the rational norms of clarity and distinctness are read as symptoms of this anxiety.[7] Bordo's social-psychological notion of maleness while rich and explicit, provides a large target for critics because it is based on a controversial historical thesis (that the 17th century showed a marked increase in gynophobia) and a disputed psychological theory of the family (Object Relations Theory).

Luce Irigaray takes a radical stance towards the history of philosophy by trying to indicate what is suppressed and hidden in the tradition rather than cataloguing its evident "maleness". Her work, like

Bordo's, makes use of psychoanalytic theory in interpreting texts and, like Lloyd's, it explores the symbolic associations of philosophical images and concepts. However, unlike Bordo and Lloyd, Irigaray uses highly unconventional methods of interpreting canonical philosophical texts in order to uncover the ways in which the feminine or sexual difference is repressed in them. For example, Irigaray uses humor and parody rather than straightforward exegesis, and she points to instabilities (contraditions) in philosophical texts as symptoms of patriarchal thinking. According to Irigaray, patriarchal thinking attempts to achieve universality by repressing sexual difference. But, the presence of contradictions or instabilities in a philosophical text is symptomatic of the failure of patriarchal thinking to contain sexual difference. For example, Irigaray might look at the argument I described above for considering gender associations with form and matter in Aristotle to be extrinsic, rather than intrinsic, to those concepts, and argue that the fact that Aristotle's hylomorphism as a universal theory is incompatible with gender associations is a symptom of patriarchal thinking rather than evidence that the proposed interpretation is mistaken.[8]

Despite their different historical stories, and the different ways that they understand the maleness of reason, each of these panoramic visions of the history of philosophy deliver the same moral, which is that the central norms that inform our philosophical culture today are gendered male.[9] Hence, these synoptic narratives of the philosophical tradition provide historical justifications for feminist philosophers who are critical of our central philosophical norms of reason and objectivity. Does the feminist synoptic critical reading of the history of philosophy justify either the conclusion that traditional conceptions of reason ought to be flat-out rejected by feminists or the conclusion that traditional conceptions of reason ought to be subjected to critical scrutiny?

Even if feminist historical arguments are successful in showing that philosophical norms like reason and objectivity are gendered male, this conclusion does not justify a flat-out rejection of either traditional philosophy or its norms of reason and objectivity (Witt 1993). Recall the distinction introduced above between intrinsically and extrinsically gendered notions. An intrinsically gendered notion is one that necessarily carries implications regarding gender, i.e., if one were to cancel all implications concerning gender, one would be left with a different notion than the original. In contrast, an extrinsically gendered notion typically does carry implications concerning gender, but not necessarily so. If the maleness of reason is extrinsic to the traditional concept of reason, then the historical fact that it was a gendered notion does not justify or require its rejection by feminists. If on the other hand, it can be shown that the maleness of reason is intrinsic to it, it still does not follow that reason ought to be rejected by feminists. For, the idea the reason is intrinsically male-biased would justify a rejection of it only if it ought to be other than it is. So, what needs to be argued is that reason and objectivity would be different, and better, if they were not gendered male, but were gender-neutral, gender-inclusive or female. But, if feminist philosophers develop this argument, which they need to buttress the historical argument, then they are reconceptualizing traditional notions of reason and objectivity rather than rejecting them.

Even though the work that feminist philosophers have done to show the ways in which traditional conceptions of reason and objectivity are associated with maleness falls short of justifying their rejection, their work has been valuable in two respects. First, it has established that gender is associated with the central norms of philosophy, a conclusion that warrants attention from anyone attempting to understand

our philosophical tradition. Second, the historical studies raise questions about reason and objectivity that are valuable areas of inquiry for contemporary philosophers.

2. Feminist Revisions of the History of Philosophy

> These women are not women on the fringes of philosophy, but philosophers on the fringes of history.
>
> ---Mary Ellen Waithe

Feminist canon revision is most distinctive, and most radical, in its retrieval of women philosophers for the historical record, and in its placement of women in the canon of great philosophers. It is a distinctive project because there is no comparable activity undertaken by other contemporary philosophical movements, for whom canon creation has been largely a process of selection from an already established list of male philosophers. It is a radical project because by uncovering a history of women philosophers, it has destroyed the alienating myth that philosophy was, and by implication is or ought to be, a male preserve.

In *A History of Women Philosophers* Mary Ellen Waithe has documented at least 16 women philosophers in the classical world, 17 women philosophers from 500-1600, and over 30 from 1600-1900.

And, in the recent feminist series *Re-reading the Canon* three of the fourteen canonical philosophers are women: Mary Wollstonecraft, Hannah Arendt and Simone de Beauvoir. What is crucial to understand is that none of the three is canonical--if by that you mean included in the history of philosophy as it is told in philosophy department curricula, in histories of philosophy, and in scholarly writing.

Indeed, *The Encyclopedia of Philosophy*, published in 1967, which contains articles on over 900 philosophers, does not include an entry for any of them. Moreover, if the index is to be believed, de Beauvoir and Wollstonecraft are not mentioned at all in any article, and Hannah Arendt merits a single mention in an article on "Authority". Far from being canonical, these women philosophers are scarcely even marginal, warranting perhaps a passing reference in a survey of existentialism or political philosophy, but little more.[10] Hence, the feminist series *Re-reading the Canon* is not only engaged in a critical re-reading of canonical figures like Plato and Hegel, but is also, by fiat, changing the contours of the canon.

The project of retrieving women philosophers has a paradoxical relationship with contemporary feminist theory, however. On the one hand, it is clearly a feminist project; its originators were interested in establishing that women have been philosophers throughout the history of the discipline despite their routine omission from standard histories and encyclopedias of philosophy. However, the newly - recovered women philosophers suggest that there is little overlap among three groups: women philosophers, feminine philosophers and feminist philosophers. For most of the newly discovered women philosophers were not feminist thinkers nor did they write philosophy in a feminine voice, different from

their male counterparts. Indeed, their breadth of philosophical interests is comparable to that of male philosophers although their domain of application sometimes differs. In her introduction to *A History of Women Philosophers* Mary Ellen Waithe comments "If we except the Pythagorean women, we find little differences in the ways men and women did philosophy. Both have been concerned with ethics, metaphysics, cosmology, epistemology and other areas of philosophic inquiry"(Waithe 1987-1991 Vol. 1: xxi). And another editor, Mary Warnock, comments "In the end, I have not found any clear "voice" shared by women philosophers (Warnock 1996: xlvii). The women philosophers restored to the tradition by feminist hands are not all proto-feminists nor do they speak in a uniform, and different, voice from their male peers.

Similarly, women philosophers who are candidates for initiation into the philosophical canon--like Mary Wollstonecraft, Hannah Arendt and Simone de Beauvoir--are a diverse crew. According to Elizabeth Young-Bruehl "That Hannah Arendt should have become a provocative subject for feminists is startling" presumably because of Arendt's explicit criticism of feminism. And while Wollstonecraft and de Beauvoir were both feminists, they share neither a common philosophical voice nor common philosophical principles. In *The Vindication of the Right's of Women* Wollstonecraft argued for the education of women using Enlightenment principles, while Beauvoir's *The Second Sex* reflects her marxist and existentialist roots.

The diversity of women philosophers raises the question why their recovery or re-valuation is an important project for contemporary feminist theory. What the retrieval of women philosophers, and their inclusion in the philosophical canon has done is to challenge the myth that there are no women in the history of philosophy and the fallback position that if there are any women philosophers, they are unimportant. Lovers of wisdom that we all are, we all benefit from the correction of these mistaken beliefs. Moreover, as feminists, we are interested in correcting the effects of discrimination against women philosophers, who were written out of history, unfairly, because of their gender not their philosophical ideas.

However, what is really at issue is not philosophy's past, but its present; its self-image as male. That self-image is created and maintained in part by a tacit historical justification. It is a damaging self-image for women philosophers today, and for women who aspire to be philosophers. The real significance of uncovering the presence of women in our history, and in placing women in our canon is the effect that has on the way we think about the "us" of philosophy.

3. Feminist Appropriation of Canonical Philosophers

Feminist philosophers have also changed the history of philosophy by appropriating its ideas for feminist purposes. From the perspective of negative canon formation, the history of philosophy is a resource only in so far as it describes the theories and thinkers that were most deeply mistaken about women. Other feminist historians of philosophy have found important resources for feminism in canonical philosophers.

Indeed, they have found valuable concepts even in the worst offenders of the negative canon, like Aristotle and Descartes.

For example, in *The Fragility of Goodness* Martha Nussbaum has described the virtues of an Aristotelian ethics with its emphasis on the importance of concrete context, emotion and care for others in an ethical life (Nussbaum 1986). And Marcia Homiak has argued that Aristotle's rational ideal, far from being antithetical to feminists, actually captures some of feminism's deepest ethical insights (Homiak 1993). With regard to Descartes, Margaret Atherton has argued that his concept of reason was interpreted in egalitarian rather than masculinist terms by several women philosophers of the 18th century, and was used in their arguments for equal education for women.[11]

Other feminists have urged the reconsideration of the views of canonical figures, like Hume and Dewey, who have played only a minor role in the negative feminist canon. For example, Annette Baier has argued at length for the value of a Humean perspective in both epistemology and in ethics for feminist theory (Baier 1987; Baier 1993). And, in *Pragmatism and Feminism* Charlene Seigfried argues for the value of pragmatism for feminism; a position also taken by Richard Rorty (Seigfried 1996; Rorty 1991).

It is interesting to note that some of the very same philosophers who were cast as the villains of the negative canon are also mined by feminist theorists for useful ideas. Indeed, it is likely that every philosopher, from Plato to Nietzsche, who has been condemned to the negative canon also appears in some feminist's positive canon. This is perplexing. After all, if feminists evaluate canonical texts so differently, it raises questions about the coherence of feminist interpretations of texts. Is Aristotle a feminist hero or villain? Are Descartes' ideas dangerous for feminists or useful to them? If feminists have argued both positions, we begin to suspect that there is no such thing as a feminist interpretation of a philosopher. And this might lead us to wonder about the coherence and unity of the project of feminist canon revision.

Why is it that feminist philosophers have reached different, and even sometimes incompatible interpretations of the history of philosophy? In my view, the multiple and contrary readings of the philosophical canon by feminists reflects the contested nature of the "us" of contemporary feminism. The fact that feminist interpretations of canonical figures is diverse reflects, and is a part of, on-going debates within feminism over its identity and self-image. Disagreements among feminist historians of philosophy over the value of canonical philosophers, and the appropriate categories to use to interpret them, are, in the final analysis, the result of debate within feminist philosophy over what feminism is, and what is theoretical committments should be, and what its core values are.

Notes to Feminist History of Philosophy

Notes

1. Phyllis Rooney summarizes feminist criticisms of the "maleness" of reason in (Rooney 1994).

2. Kant's derogatory remarks about women are in his pre-critical work *Observations on the Beautiful and Sublime* p. 111 (Goldthwaite ed.). Robin Schott presents a critical, feminist reading of Kant's conceptual framework in (Schott 1988).

3. Feminists use the idea of a gendered notion to mean different things. In this article I draw a distinction between holding that a notion is intrinsically gendered, and holding that it is extrinsically gendered. Other feminists, however, use the idea of a gendered notion in ways that do not map easily onto my distinction. For example, as I discuss below, Genevieve Lloyd argues for the symbolic gendering of philosophical notions, and it may be that her interpretation does not map onto the intrinsic/extrinsic distinction. And Sally Haslanger argues that objectivity is a gendered notion in the philosophy of Catharine MacKinnon in a way that is neither extrinsic nor intrinsic.

4. (Tuana 1992) also provides a feminist reading of the history of philosophy.

5. (Keller 1985) is a classic source for feminist criticism of the rise of modern science.

6. (Lloyd 1993b, ix). In another essay Lloyd explains that in her view there is an important connection between gender metaphors in philosophical texts and real world gender divisions and the way that gender identity is formed in a culture. See (Lloyd 1993a).

7. In (Scheman 1993), Naomi Scheman develops parallels between the Cartesian subject--disembodied, rational, and unitary--and the repression and projection characteristic of paranoia. Her analysis, like Bordo's, makes use of psychoanalytic categories but it does not make a historical, cultural claim as Bordo does.

8. For a discussion of Irigaray's contribution to feminist scholarship on the history of philosophy see (Deutscher 1997).

9. Bordo and Lloyd differ in other important respects as well. Bordo is interested in providing a social and psychological explanation for the masculinization of philosophy by Descartes. Why did Descartes conceive of reason and objectivity in a masculine guise? The social answer is that during his life

European culture was undergoing a gynophobic spasm. The psychological answer depends upon object relations theory, and the development of that theory along gender lines by Chodorow and others. Lloyd is not interested primarily in the causal question addressed by Bordo. Moreover, she thinks that the maleness of reason in the philosophical tradition is primarily symbolic or metaphorical rather than social or psychological. Ultimately, then Bordo and Lloyd differ as to what is meant by the maleness of reason.

10. For a discussion of the omission of Simone de Beauvoir from the philosophical canon see the introduction to (Simons 1995).

11. 11. (Atherton 1993). Celia Amorós has retrieved the arguments in support of the equality of the sexes made by the 17th century Cartesian philosopher Francois Poullain de la Barre (1647-1723). See (Amorós 1994).

Many-Valued Logic

Many-valued logics are non-classical logics. They are similar to classical logic because they accept the principle of truth-functionality, namely, that the truth of a compound sentence is determined by the truth values of its component sentences (and so remains unaffected when one of its component sentences is replaced by another sentence with the same truth value). But they differ from classical logic by the fundamental fact that they do not restrict the number of truth values to only two: they allow for a larger set *W* of truth degrees.

Just as the notion of ‘possible worlds’ in the semantics of modal logic can be reinterpreted (e.g., as ‘moments of time’ in the semantics of tense logic or as ‘states’ in the semantics of dynamic logic), there does not exist a standard interpretation of the truth degrees. How they are to be understood depends on the actual field of application. It is general usage, however, to assume that there are two particular truth degrees, usually denoted by "0" and "1", respectively, which act like the traditional truth values "falsum" and "verum".

The formalized languages for systems of *many-valued logic* (MVL) follow the two standard patterns for propositional and predicate logic, respectively:

- there are propositional variables together with connectives and (possibly also) truth degree constants in the case of propositional languages,
- there are object variables together with predicate symbols, possibly also object constants and function symbols, as well as quantifiers, connectives, and (possibly also) truth degree constants in the case of first-order languages.

As usual in logic, these languages are the basis for semantically as well as syntactically founded systems of logic.

Semantics

There are two kinds of semantics for systems of many-valued logic.

We discuss these in turn.

Standard Logical Matrices

The most suitable way of defining a system **S** of many-valued logic is to fix the characteristic logical matrix for its language, i.e. to fix:

* the set of truth degrees,
* the truth degree functions which interpret the propositional connectives,
* the meaning of the truth degree constants,
* the semantical interpretation of the quantifiers,

and additionally,

* the *designated truth degrees*, which form a subset of the set of truth degrees and act as substitutes for the traditional truth value "verum".

A well-formed formula *A* of a propositional language counts as *valid* under some valuation α (which maps the set of propositional variables into the set of truth degrees) iff it has a designated truth degree under α. And *A* is *logically valid* or a *tautology* iff it is valid under all valuations.

In the case of a first-order language, such a well-formed formula *A* counts as *valid* under an interpretation α of the language iff it has a designated truth degree under this interpretation and all assignments of objects from the universe of discourse of this interpretation to the object variables. *A* counts as *logically valid* iff it is valid under all interpretations.

Like in classical logic, such an interpretation has to provide

* a (non empty) universe of discourse,

- the meaning of the object constants of the language,
- the meaning of the predicate letters and the function symbols of the language.

A *model* of some set Σ of well-formed formulas is a valuation α or an interpretation α such that all $A \in \Sigma$ are valid under α . That Σ *entails* *A* means that each model of Σ is also a model of *A*.

Algebraic Semantics

There is a second type of semantics for systems **S** of many-valued logic which is based on a whole characteristic class **K** of (similar) algebraic structures. Each such algebraic structure has to provide all the data which have to be provided by a characteristic logical matrix for the language of **S**.

The notion of validity of a formula *A* with respect to an algebraic structure from **K** is defined as if this structure would form a logical matrix. And *logical validity* here means validity for all structures from the class **K**.

The type of algebraic structures which may form such a characteristic class **K** for some system **S** of MVL is usually determined by the (syntactical or semantical) Lindenbaum algebra of **S**, and often plays also a crucial role within an algebraic completeness proof. The algebraic structures in **K** have a similar role for **S** as the Boolean algebras do for classical logic.

For particular systems of MVL one has e.g. the following characteristic classes of algebraic structures:

- for infinite valued *Lukasiewicz logic* the class of MV-algebras,
- for infinite valued *Gödel logic* the class of all Heyting algebras which satisfy prelinearity $(x \rightarrow y) \cup (y \rightarrow x) = 1$,
- for Hajek's *basic t-norm logic* the class of all divisible residuated lattices which satisfy prelinearity.

From a philosophical point of view, it would be preferable to have a semantic foundation for a system of MVL which uses a characteristic logical matrix. However, from a formal point of view, both approaches are equally important, and the algebraic semantics turns out to be the more general approach.

Proof Theory

The main types of logical calculi are all available for systems of MVL:

- Hilbert type calculi

- Gentzen type sequent calculi
- Tableau calculi

However, some of the above are available only for finitely valued systems.

Hilbert type calculi. These calculi are formed in the same way as the corresponding calculi for classical logic: some set of *axioms* is used together with a set of *inference rules*. The notion of derivation is the usual one.

Gentzen type sequent calculi. In addition to the usual types of sequent calculi, researchers have also recently started to discuss ‘hypersequent’ calculi for systems of MVL. Hypersequents are finite sequences of ordinary sequents.

For finitely valued systems, particularly *m*-valued ones, there are also sequent calculi which work with *generalized sequents*. In the *m*-valued case, these are sequences of length *m*.

Tableau calculi. The tree structure of the tableaux remains the same in these calculi as in the tableau calculi for classical logic. The labels of the nodes become more general objects, namely, *signed formulas*. A signed formula is a pair, consisting of a *sign* and a well-formed formula. A sign is either a truth degree, or a set of truth degrees.

Tableau calculi with signed formulas are usually restricted to finite-valued systems of MVL, so that they can be dealt with in an effective way.

[Return to Table of Contents]

Systems of Many-Valued Logic

The main systems of MVL often come as families which comprise uniformly defined finite-valued as well as infinite-valued systems. Here is a list:

- Lukasiewicz logics
- Gödel logics
- t-Norm related systems
- 3-valued systems
- Dunn/Belnap's 4-valued system
- Product systems

Lukasiewicz logics

The systems L_m and L_∞ are defined by the logical matrix which has either some finite set

$$W_m = \{k/m-1 \mid 0 \leq k \leq m-1\}$$

of rationals within the real unit interval, or the whole unit interval

$$W_\infty = [0,1] = \{x \in R \mid 0 \leq x \leq 1\}$$

as the truth degree set. The degree 1 is the only designated truth degree.

The main connectives of these systems are a strong and a weak conjunction, & and $\wedge$, respectively, given by the truth degree functions

$$u \mathbin{\&} v = \max\{0, u + v - 1\},$$

$$u \wedge v = \min\{u, v\},$$

a negation connective $\neg$ determined by

$$\neg u = 1 - u,$$

and an implication connective $\rightarrow$ with truth degree function

$$u \rightarrow v = \min\{1, 1 - u + v\}.$$

Often, two disjunction connectives are also used. These are defined in terms of & and $\wedge$, respectively, via the usual de Morgan laws using $\neg$. For the first-order Lukasiewicz systems one adds two quantifiers $\forall$, $\exists$ in such a way that the truth degree of $\forall x H(x)$ is the *infimum* of all the relevant truth degrees of $H(x)$, and that the truth degree of $\exists x H(x)$ is the *supremum* of all the relevant truth degrees of $H(x)$.

Gödel logics

The systems G_m and G_∞ are defined by the logical matrix which has either some finite set

$$W_m = \{k/m-1 \mid 0 \leq k \leq m-1\}$$

of rationals within the real unit interval, or the whole unit interval

$$W_\infty = [0,1] = \{x \in R \mid 0 \leq x \leq 1\}$$

as the truth degree set. The degree 1 is the only designated truth degree.

The main connectives of these systems are a conjunction $\wedge$ and a disjunction $\vee$ determined by the truth degree functions

$$u \wedge v = \min\{u, v\},$$

$$u \vee v = \max\{u, v\},$$

an implication connective $\rightarrow$ with truth degree function

$$u \rightarrow v = \begin{cases} 1, & \text{if } u \leq v \\ v, & \text{if } u > v \end{cases}$$

and a negation connective $\sim$ with truth degree function

$$\sim u = \begin{cases} 1, & \text{if } u = 0 \\ 0, & \text{if } u \neq 0 \end{cases}$$

For the first-order Gödel systems one adds two quantifiers $\forall$, $\exists$ in such a way that the truth degree of $\forall x H(x)$ is the *infimum* of all the relevant truth degrees of $H(x)$, and that the truth degree of $\exists x H(x)$ is the *supremum* of all the relevant truth degrees of $H(x)$.

t-Norm related systems

For infinite valued systems with truth degree set

$$W_\infty = [0,1] = \{x \in \mathbb{R} \mid 0 \leq x \leq 1\}$$

the influence of fuzzy set theory quite recently initiated the study of a whole class of such systems of MVL.

These systems are basically determined by a (possibly non-idempotent) strong conjunction connective $\&_T$ which has as corresponding truth degree function a *t-norm* T, i.e. a binary operation T in the unit interval which is associative, commutative, non-decreasing, and has the degree 1 as a neutral element:

- $T(u,T(v,w)) = T(T(u,v),w)$,
- $T(u,v) = T(v,u)$,

- $u \leq v \Rightarrow \mathrm{T}(u,w) \leq \mathrm{T}(v,w)$,
- $\mathrm{T}(u,1) = u$.

For all those t-norms which have the *sup-preservation property*

$$\mathrm{T}(u, \sup_i v_i) = \sup_i \mathrm{T}(u,v_i),$$

there is a standard way to introduce a related implication connective $\rightarrow_{\mathrm{T}}$ with the truth degree function

$$u \rightarrow_{\mathrm{T}} v = \sup \{z \mid \mathrm{T}(u,z) \leq v\}.$$

This is connected with the t-norm T by the crucial *adjointness condition*

$$\mathrm{T}(u,v) \leq w \Leftrightarrow u \leq (v \rightarrow_{\mathrm{T}} w),$$

which determines $\rightarrow_{\mathrm{T}}$ uniquely for each T with sup-preservation property.

The language is further enriched with a negation connective, $-_{\mathrm{T}}$, determined by the truth degree function

$$-_{\mathrm{T}} u = u \rightarrow_{\mathrm{T}} 0.$$

This forces the language to have also a truth degree constant $\underline{0}$ to denote the truth degree 0 because then $-_{\mathrm{T}}$ becomes a definable connective.

Usually one adds as two further connectives a (weak) conjunction $\wedge$ and a disjunction $\vee$ with truth degree functions.

$$u \wedge v = \min \{u, v\},$$

$$u \vee v = \max \{u, v\}.$$

Particular cases of such t-norm related systems are the infinite valued Lukasiewicz and Gödel systems L_∞, G_∞, and also the *product logic* which has the usual arithmetic product as its basic t-norm.

The class of all t-norms, even of those which have the sup-preservation property, is very large. Actually one is able to axiomatize t-norm based systems for some particular classes of t-norms. And Hajek (1998) has given an axiomatization of the logic which has as its algebraic semantics the class of all t-norm based structures whose t-norm is a continuous function.

The axiomatization of further t-norm based systems, as well as the question for t-norm based quantifiers,

are recent research problems.

3-valued systems

3-valued systems seem to be particularly simple cases which offer intuitive interpretations of the truth degrees; these systems include only one additional degree besides the classical truth values.

The mathematician and logician Kleene used a third truth degree for "undefined" in the context of partial recursive functions. His connectives were the negation, the weak conjunction, and the weak disjunction of the 3-valued Lukasiewicz system together with a conjunction $\wedge_+$ and an implication $\rightarrow_+$ determined by truth degree functions with the following function tables:

$\wedge_+$	0	½	1
0	0	½	0
½	½	½	½
1	0	½	1

$\rightarrow_+$	0	½	1
0	1	1	1
½	½	½	½
1	0	½	1

Here ½ is the third truth degree "undefined". In this Kleene system, the degree 1 is the only designated truth degree.

Blau (1978) used a different system as an inherent logic of natural language. In Blau's system, both degrees 1 and ½ are designated. Other interpretations of the third truth degree ½, for example as "senseless", "undetermined", or "paradoxical", motivated the study of other 3-valued systems.

Dunn/Belnap's 4-valued system

This particularly interesting system of MVL was the result of research on relevance logic, but it also has significance for computer science applications. Its truth degree set may be taken as

$$W^* = \{\emptyset, \{\bot\}, \{\top\}, \{\bot, \top\}\},$$

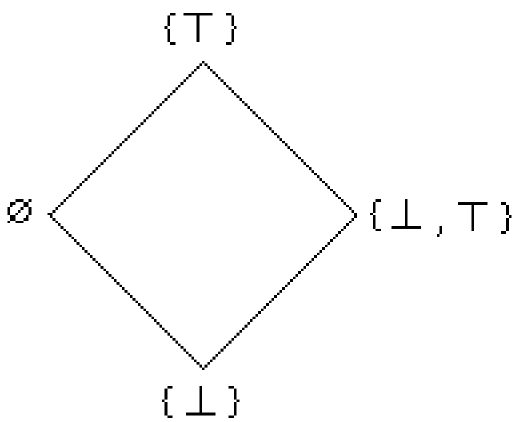
and the truth degrees interpreted as indicating (e.g. with respect to a database query for some particular

state of affairs) that there is

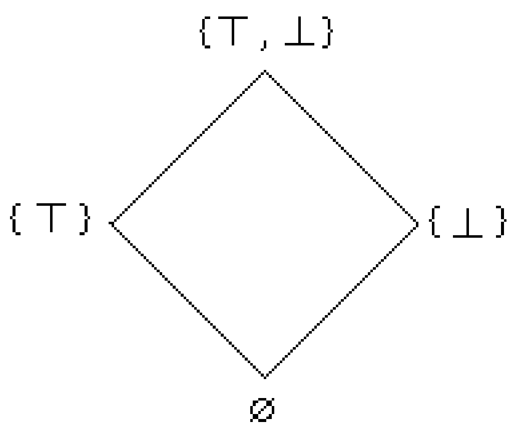
- no information concerning this state of affairs,
- information saying that the state of affairs fails,
- information saying that the state of affairs obtains,
- conflicting information saying that the state of affairs obtains as well as fails.

This set of truth degrees has two natural (lattice) orderings:

- a *truth ordering* which has $\{\top\}$ on top of the incomparable degrees $\emptyset$, $\{\bot , \top\}$, and has $\{\bot\}$ at the bottom; i.e.,



- an *information* (or: *knowledge*) *ordering* which has $\{\bot , \top\}$ on top of the incomparable degrees $\{\bot\}$, $\{\top\}$, and has $\emptyset$ at the bottom; i.e.,



Given the inf and the sup under the truth ordering, there are truth degree functions for a conjunction and a disjunction connective. A negation is, in a natural way, determined by a truth degree function which exchanges the degrees $\{\bot\}$ and $\{\top\}$, and which leaves the degrees $\{\bot , \top\}$ and $\emptyset$ fixed.

Actually, there is no standard candidate for a implication connective, and the choice of the designated truth degrees depends on the intended applications:

- for computer science applications it is natural to have $\{\top\}$ as the only designated degree,

- for applications to relevance logic the choice of {⊤}, {⊥ , ⊤} as designated degrees proved to be adequate.

The choice of suitable entailment relations is still an open research topic.

Product systems

The general problem of finding an intuitive understanding of the truth degrees occasionally has a nice solution: one can consider them as comprising different aspects of the evaluation of sentences. In such a case of, say, *k* different aspects the truth degrees may be chosen as *k*-tuples of values which evaluate the single aspects. (And these, e.g., may be standard truth values.)

The truth degree functions over such *k*-tuples additionally can be defined "componentwise" from truth degree (or: truth value) functions for the values of the single components. In this manner, *k* logical systems may be combined into one many-valued *product system*.

In this way, the truth degrees of Dunn/Belnap's 4-valued system can be considered as evaluating two aspects of a state of affairs (SOA) related to a database:

1. whether there is positive information about the truth of this SOA or not, and
2. whether there is positive information about the falsity of this SOA or not.

Both aspects can use standard truth values for this evaluation.

In this case, the conjunction, disjunction, and negation of Dunn/Belnap's 4-valued system are componentwise definable by conjunction, disjunction, or negation, respectively, of classical logic, i.e. this 4-valued system is a product of two copies of classical two-valued logic.

Applications of Many-Valued Logic

Many-valued logic was motivated in part by philosophical goals which were never achieved, and in part by formal considerations concerning functional completeness. In the earlier years of development, this caused some doubts about the usefulness of MVL. In the meantime, however, interesting applications were found in diverse fields. Some of these shall now be mentioned.

Applications to Linguistics. A challenging problem is the treatment of presuppositions in linguistics, i.e. of assumptions that are only implicit in a given sentence. So, for example, the sentence "The present king of Canada was born in Vienna" has the *existential presupposition* that there is a present king of Canada.

It is not a simple task to understand the propositional treatment of such sentences, e.g. to give criteria for forming their negation, or understanding the truth conditions of implications.

One type of solution for these problems refers to the use of many truth degrees, e.g. to *product systems* with ordered pairs as truth degrees: meaning that their components evaluate in parallel whether the presupposition is met, and whether the sentence is true or false. But 3-valued approaches have also been discussed.

Applications to Logic. A first type of application of systems of MVL to logic itself is to use them to gain a better understanding of other systems of logic. In this way the Gödel systems arose out of an approach to test whether intuitionistic logic may be understood as a finitely valued logic. The introduction of systems of MVL by Lukasiewicz (1920) was initially guided by the (finally unsuccessful) idea of understanding the notion of possibility, i.e. modal logic, in a 3-valued way.

A second type of application to logic is the merging of different types of logical systems, e.g. the formulation of systems with graded modalities. Melvin Fitting (1991/92) considers systems that define such modalities by merging modal and many-valued logic, with intended applications to problems of Artificial Intelligence.

A third type of application to logic is the modeling of partial predicates and truth value gaps. However, this is possible only in so far as these truth value gaps behave "truth functionally", i.e. in so far as the behavior of the truth value gaps in compound sentences can be described by suitable truth functions. (This is not always the case, e.g. it is not the case in formulations which use *supervaluations*.)

Applications to Philosophical Problems . How to understand the meaning of "truth" is an old philosophical problem. A logical approach toward this problem consists in enriching a formalized language L with a truth predicate T, to be applied to sentences of L -- or, even better, to be applied to sentences of the extension L_T of L with the predicate T.

Based upon this idea, a reasonable theory of such languages which contain truth predicates was developed in the mid-1930s by A. Tarski. One of the results was that such a language L_T, which contains its own truth predicate T and has a certain richness in expressive power, is necessarily inconsistent.

Another approach toward such languages L_T which contain their own truth predicate T was offered by S. Kripke (1975) and is essentially based upon the idea of considering T as a partial predicate, i.e. as a predicate which has "truth value gaps". In a case Kripke (1975) considers, these truth value gaps behave "truth functionally" and so can be treated like a third truth degree. Their propagation in compound sentences then becomes describable by suitable truth degree functions of three-valued systems. In Kripke's (1975) approach this reference was to three-valued systems which S. C. Kleene (1938) had considered in the (mathematical) context of partial functions and predicates in recursion theory.

A second application of MVL inside philosophy is to the old paradoxes like the *Sorites* (heap) or the *falakros* (bald man). (See the entry Sorites paradox.) In the case of the Sorites, the paradox is as follows:

> (i) One grain of sand is not a heap of sand. And (ii) adding one grain of sand to something which is not a heap does not turn it into a heap. Hence (iii) a single grain of sand can never turn into a heap of sand, no matter how many grains of sand are added to it.

Thus the true premise (i) gives a false conclusion (iii) via a sequence of inferences using (ii). A rather natural solution inside an extension of MVL with a graded notion of inference, often called *fuzzy logic*, is to take the notion of heap as a *vague* one, i.e. as a notion which may hold true of given objects only to some (truth) degree. Additionally it is suitable to consider premise (ii) as only partially true, however to a degree which is quite near to the maximal degree 1. Then each single inference step is of the form:

- (a): *k grains of sand do not make a heap.*
- (ii): *Adding one grain of sand to k grains does not make (k+1) grains into a heap.*
- Hence (b): *(k+1) grains of sand do not make a heap.*

However, this inference has to involve truth degrees for the premises (a) and (ii), and has to provide a truth degree for the conclusion (b). The crucial idea for the modeling of this type of reasoning inside MVL is to make sure that the truth degree for (b) is smaller than the truth degree for (a) in case the truth degree for (ii) is smaller than the maximal one. In effect, then, the sentence *n grains of sand do not make a heap* tends toward being false for an increasing number *n* of grains.

Applications to Hardware Design. Classical propositional logic is used as a technical tool for the analysis and synthesis of some types of electrical circuits built up from "switches" with two stable states, i.e. voltage levels. A rather straightforward generalization allows the use of an *m*-valued logic to discuss circuits built from similar "switches" with *m* stable states. This whole field of application of many-valued logic is called many-valued (or even: fuzzy) switching. A good introduction is Epstein (1993).

Applications to Artificial Intelligence. AI is actually the most promising field of applications, which offers a series of different areas in which systems of MVL have been used.

A first area of application concerns vague notions and commonsense reasoning, e.g. in expert systems. Both topics are modeled via fuzzy sets and fuzzy logic, and these refer to suitable systems of MVL. Also,

in databases and in knowledge-based systems one likes to store vague information.

A second area of application is strongly tied with this first one: the automatization of data and knowledge mining. Here clustering methods come into consideration; these refer via unsharp clusters to fuzzy sets and MVL. In this context one is also interested in automated theorem proving techniques for systems of MVL, as well as in methods of logic programming for systems of MVL.

Applications to Mathematics. There are three main topics inside mathematics which are related to many-valued logic. The first one is the mathematical theory of fuzzy sets, and the mathematical analysis of "fuzzy", or approximate reasoning. In both cases one refers to systems of MVL. The second topic has been approaches toward consistency proofs for set theory using a suitable system of MVL. And there is an -- often only implicit -- reference to the basic ideas of MVL in independence proofs (e.g. for systems of axioms) which often refer to logical matrices with more than two truth degrees. However, here MVL is more a purely technical tool because in these independence proofs one is not interested in an intuitive understanding of the truth degrees at all.

History of Many-Valued Logic

Many-valued logic as a separate subject was created by the Polish logician and philosopher Lukasiewicz (1920), and developed first in Poland. His first intention was to use a third, additional truth value for "possible", and to model in this way the modalities "it is necessary that" and "it is possible that". This intended application to modal logic did not materialize. The outcome of these investigations are, however, the Lukasiewicz systems, and a series of theoretical results concerning these systems.

Essentially parallel to the Lukasiewicz approach, the American mathematician Post (1921) introduced the basic idea of additional truth degrees, and applied it to problems of the representability of functions.

Later on, Gödel (1932) tried to understand intuitionistic logic in terms of many truth degrees. The outcome was the family of Gödel systems, and a result, namely, that intuitionistic logic does not have a characteristic logical matrix with only finitely many truth degrees. A few years later, Jaskowski (1936) constructed an infinite valued characteristic matrix for intuitionistic logic. It seems, however, that the truth degrees of this matrix do not have a nice and simple intuitive interpretation.

A philosophical application of 3-valued logic to the discussion of paradoxes was proposed by the Russian logician Bochvar (1938), and a mathematical one to partial function and relations by the American logician Kleene (1938). Much later Kleene's connectives also became philosophically interesting as a technical tool to determine fixed points in the revision theory of truth initiated by Kripke (1975).

The 1950s saw (i) an analytical characterization of the class of truth degree functions definable in the infinite valued propositional Lukasiewicz system by McNaughton (1951), (ii) a completeness proof for the same system by Chang (1958, 1959) introducing the notion of MV-algebra and a more traditional one by Rose/Rosser (1958), as well as (iii) a completeness proof for the infinite valued propositional Gödel system by Dummett (1959). The 1950s also saw an approach of Skolem (1957) toward proving the consistency of set theory in the realm of infinite valued logic.

In the 1960s, Scarpellini (1962) made clear that the first-order infinite valued Lukasiewicz system is not (recursively) axiomatizable. Hay (1963) as well as Belluce/Chang (1963) proved that the addition of one infinitary inference rule leads to an axiomatization of L_∞. And Horn (1969) presented a completeness proof for first-order infinite valued Gödel logic. Besides these developments inside pure many-valued logic, Zadeh (1965) started an (application oriented) approach toward the formalization of vague notions by generalized set theoretic means, which soon was related by Goguen (1968/69) to philosophical applications, and which later on inspired also a lot of theoretical considerations inside MVL.

The 1970s mark a period of restricted activity in pure many-valued logic. There was, however, a lot of work in the closely related area of (computer science) applications of vague notions formalized as fuzzy sets, initiated e.g. by Zadeh (1975, 1979). And there was an important extension of MVL by a graded notion of inference and entailment in Pavelka (1979).

In the 1980s, fuzzy sets and their applications remained a hot topic that called for theoretical foundations by methods of many-valued logic. In addition, there were the first complexity results e.g. concerning the set of logically valid formulas in first-order infinite valued Lukasiewicz logic, by Ragaz (1983). Mundici (1986) started a deeper study of MV-algebras.

These trends have continued since the 1980s. Research has included applications of MVL to fuzzy set theory and their applications, detailed investigations of algebraic structures related to systems of MVL, the study of graded notions of entailment, and investigations into complexity issues for different problems in systems of MVL. This research was complemented by interesting work on proof theory, on automated theorem proving, by different applications in artificial intelligence matters, and by a detailed study of infinite valued systems based on t-norms.

Philip the Chancellor

Philip the Chancellor was an influential figure in a number of different circles in the first half of the thirteenth century. He enjoyed a long though rather turbulent ecclesiastical career and was famous for his sermons and his lyric poetry, the latter of which has received attention by a number of musicologists in recent years. In the areas of philosophy and theology, his major work, *Summa de bono*, which was composed sometime in the 1220s-1230s, was a ground-breaking achievement in many ways. Philip was one of the first to organize a *Summa* around a central foundational principle, the notion of the good. *Summa de bono* also contains most likely the earliest treatment of a topic that rose to prominence in the later medieval period, the doctrine of the transcendentals. Elements of Philip's theory of action drew comments from such later notables as Albert the Great. *Summa de bono* was a well-respected and influential work in the thirteenth century.

Philip's Life

Philip was born in Paris probably in the 1160s, the exact date unknown. He was a member of a prominent Parisian family; many of his relatives held important positions, in service to the French kings or to the church. Several were bishops of prominent sees, in particular, his uncle, Peter of Nemours, who was bishop of Paris from 1208 to 1218 and who helped to foster Philip's career. Most likely, Philip received his education at the nascent University of Paris, where he also taught. Sometime in the early 1200s, he was appointed the archdeacon of Noyon, a position he held even after becoming chancellor of the Cathedral of Notre Dame in Paris in 1217. Philip died in 1236, most likely on December 26.

Philip's Career as Chancellor

The position of chancellor at the cathedral of Notre Dame in Paris was one of some importance, although it was the lowest ranking office in the administrative hierarchy of the chapter. Minor duties included keeping the official seal of the chapter, executing the official decrees of the administrative body, maintaining the non-musical books of the library, and serving in the liturgy of the daily office. His most significant responsibility was in the area of education. The chancellor was originally the head of the cathedral school. As masters began to flock to Paris in the late twelfth and early thirteenth centuries, especially to the Ile-de-la-Cite, where Notre Dame is located, the chancellor's supervision was extended to include these masters as well. His power lay in his authority to grant the teaching license, which was required in order to hold classes in one of the schools springing up on the Ile-de-la-Cite. It was the chancellor's duty to evaluate candidates applying for this license. Moreover, the chancellor had the right to revoke the license should a master prove unworthy or incompetent, as well as the responsibility for maintaining order and discipline among the scholars within his jurisdiction.

By the time Philip became chancellor in 1217, the masters of the various schools in Paris had begun to seek autonomy from the cathedral chapter and had won a number of important concessions by papal decree. In 1215, the papal legate, Robert of Courcon, drew up a number of formal statutes, codifying the *de facto* practices regarding matters such as the examinations for teaching licenses, accepted dress and behavior, curriculum, and discipline of students. As a result, by the time that Philip became chancellor, at least on paper, it appeared as if the power of his office had been greatly reduced, even with respect to granting the teaching license. For although the chancellor retained the power to grant these licenses, the statutes dictated that he could not turn down anyone the masters deemed fit to teach. But in reality, a long struggle ensued between the masters and the chancellor, who sought to retain his power, beginning with Philip's predecessor (Stephen of Reims) and continuing into much of Philip's own tenure. Finally, in the late 1220s and early 1230s, Philip made his peace with the masters, who had gone on strike and left Paris along with many of their students in response to a conflict with the secular authorities. No doubt recognizing that their departure imperiled the continuing prestige of Paris as a center of education, as well as his own position, Philip worked hard to convince the scholars to return to Paris and reconvene their classes. His efforts were successful, and the masters returned in 1231.

Philip's Philosophical Significance

In his major philosophical work, *Summa de bono*, Philip uses the notion of the good as an organizing principle for his study. He divides the text roughly into four sections. Philip discusses first the nature of good in general terms, and then the highest good and its relationship to created goods. After this rather short introduction to the notion of the good, Philip goes on to examine in some depth the various sorts of created goods. He divides his discussion of created goods into three parts. First, he looks at the good retained by creatures by virtue of their natures (*bonum naturae*). In turn, these goods fall into two categories: those goods that cannot be diminished by evil and those goods that can be lost through evil. In his discussion of the former, Philip focuses first on the angels and their properties, and then on human

beings and their properties. Those goods that can be affected by evil are discussed in conjunction with Adam's fall from grace in the Garden and its consequences. Following the discussion of *bonum naturae*, Philip considers what he calls *bonum in genere*. Although this sort of good has a rather peculiar title, the *bonum in genere* represents goods that come about as a result of an agent's actions. These goods have this title because what determines whether a given act is good depends not only on the sort of act it is (its "form" so to speak) but also what the act has to do with (its "matter" so to speak), thus suggesting that these sorts of goods can be classified along the lines of genera and species. Moreover, these sorts of generic goods contrast with the meritorious goods brought about as the result of God's grace. After discussing the *bonum in genere*, Philip goes on to look at the good that is associated with grace. Here, he divides his treatment into the graces that pertain to angels (as well as their ministries) and the graces that pertain to human beings. Philip includes the virtues in his discussion of human graces. Although he denies that the virtues are a type of grace, he includes them in this section because virtues come about as a result of grace working within human beings. This idea is most naturally associated with the theological virtues of faith, hope, and charity, and indeed, Philip discusses these virtues here at some length. But he also includes in this section a lengthy discussion of the cardinal virtues: prudence, fortitude, temperance (and the associated virtues of modesty, sobriety, continence, and virginity), and justice, virtues which one might argue have no direct connection with grace. Philip admits that strictly speaking cardinal virtues are not divine virtues since they have to do with what is for the sake of the end and not directly with the end itself (the end of course being God). But he argues that justice has to do both with God and with human governance; perhaps because of this connection, Philip felt justified in including them in a broader discussion of grace. Philip ends his work with another source of grace, the seven gifts of the Holy Spirit. Philip's discussion of the good of grace in human beings occupies over half of *Summa de bono* with his unit on the virtues accounting for a large portion of this section.

Philip's *Summa de bono* represents a significant innovation in medieval philosophical work. His use of the good as an organizing principle is a departure from the explicitly theological structure of other well-known texts of the time including Peter Lombard's *Sentences* and William of Auxerre's *Summa aurea*. Philip is certainly concerned with theological issues, but unlike the *Sentences* or the *Summa aurea*, Philip devotes no significant sections of his work to topics such as God's nature, the Incarnation, or the sacraments. Furthermore, whereas often William's or Lombard's examination of a philosophical issue arises in the context of a larger theological issue, this is not always the case for Philip. For example, in William's *Summa aurea*, the issues of human action and its freedom arise within a discussion of Adam's fall in the Garden. William raises these issues here because he recognizes that holding Adam responsible for his sin requires that Adam acted freely. Philip places his treatment of free action within an examination of human psychology. It is not until after Philip discusses the character and the powers of the human soul that he gets around to examining theological issues such as the origin and the immortality of the soul. Philip is one of the first major thinkers in the Latin West whose work reflects the influence of the recent influx of newly translated texts from Aristotle and his Arabic commentators, particularly in the area of metaphysics. This may help to explain the distinctive character of his work. Philip's use of Aristotelian metaphysics is especially interesting given that many of Aristotle's metaphysical treatises and work in natural philosophy were officially banned at Paris during the time that Philip was working on *Summa de bono*.

Philip's Innovative Theory of the Transcendentals

Philip's influence in the thirteenth century was especially felt in the area of the transcendentals and in action theory. In this section, I will consider his theory of the transcendentals. I will examine his theory of action in the following section. To some extent, the doctrine of the transcendentals has its roots in the Christian-Platonic discussions of the relationship between created and divine being and goodness, in particular, in William of Auxerre's treatment of goodness prefatory to his examination of the virtues in *Summa aurea*. However, its more immediate ancestor is Aristotle's doctrine of the categories. Certain properties fall into none of Aristotle's categories; rather they are properties of all of the things to which the categories are applicable. For this reason, these properties are said to "transcend" the categories. Although there is some variation in what is counted as a transcendental, the list generally included being, unity, truth, and goodness. Thus, everything that falls into any of Aristotle's categories is a being, has a certain sort of unity, and is true and good to a certain extent.

Not only do these properties transcend the categories and as a result, apply to everything classified by the categories, but they are held to be convertible with each other as well. This could mean one of two things. The transcendentals could be coextensional, so that whatever has being also has unity, truth, and goodness. This leaves open the possibility that the transcendentals are separate and distinct from one another. The second option of the convertibility thesis involves a stronger claim, namely, the idea that the transcendentals differ from one another only in concept, not in reality. Unity, truth, and goodness add nothing to a particular being over and above what is already there; everything that is a being is also one, true, and good in virtue of the very same characteristics. But to describe something as a being and to describe it as, say, good is to express two different things about it since the concept of a being and the concept of a good are two very different concepts. Thus, while being and goodness are extensionally equivalent, they are intensionally distinct.

Philip adopts the second notion of convertibility. The various transcendentals do not differ in reality, only in concept. The concept of being is fundamental in that the concepts of the other transcendentals presuppose it. However, the concepts of all of the other transcendentals add a certain basic notion to the notion of being in order to differentiate them from being. This basic notion is the notion of being that is undivided. Because this is a purely negative notion, it picks out no additional property in reality. The addition of indivision alone yields the concept of unity. To derive the concepts of the true and the good, one adds further the notion of the appropriate cause. The concept of truth involves the idea of the formal cause, that is, the cause in virtue of which matter is enformed, and a thing becomes what it is. Things are true, that is, genuine instances of the kind of thing they are to the extent that they instantiate the form of things of that kind. Thus, the concept of truth is the concept of being that is undivided from a formal cause. Goodness, on the other hand, has to do with being that is undivided from a final cause, that is, a cause that has to do with goals or ends, especially those goals that have been brought to fulfillment. Everything has a particular nature, that is, properties that make that thing a thing of that type. But things can exemplify those properties to a greater or lesser extent. Philip claims that everything has as its goal its own perfection, which means that things move toward exemplifying their specifying characteristics to the greatest extent possible. To the extent that a thing does so, that thing will be good. But that thing will

also have being to the same extent. Thus, goodness and being in a given thing coincide in reality, and a thing's goodness adds nothing over and above the thing's being. But of course, goodness and being involve two different concepts. Thus, being and goodness have the same extension while differing intensionally.

It has been argued (by Pouillion and others) that Philip's discussion of the transcendentals in *Summa de bono* represents the earliest formal treatise on the transcendentals in the history of Western philosophy. About ten years earlier, William of Auxerre also discussed the relationship between being and goodness; he raises the issue of whether being and being good are the same. But in resolving this issue, William never considers the central issue of the transcendentals, the idea that they are extensionally equivalent while intensionally different. It appears that Philip is the first to do so. MacDonald argues that Philip's greater familiarity with the metaphysical works of Aristotle and the Arabic commentators accounts for the startling innovations of his work on the transcendentals. It is likely that Philip encountered the fundamental notion of extensional equivalence and intensional difference in the work of the Arabic commentators of Aristotle; both Avicenna and Averroes argue that unity and being have the same extension while differing conceptually. Philip extends this idea to include not only being and unity, but also the true and the good. Philip's work in turn sets the stage for the development of this topic throughout the thirteenth century, influencing the work of such notable thinkers as Alexander of Hales, Albert the Great, and Thomas Aquinas.

Philip's Psychology

Although not as well known, Philip's psychology also exhibits some innovative features and influenced later thinkers, in particular, Albert the Great. In the early thirteenth century, theorists accounted for human abilities by arguing that in order to do what they do, agents must possess certain capacities or powers. Thus for every ability, there must be a corresponding and separate power. Human beings have the ability to think; therefore, they must have a cognitive power, often called intellect or reason. Medieval philosophers also adopted Aristotle's distinction between practical intellect, which discerns what to do, and speculative intellect, which discerns the truth about the way things are. Human beings have the capacity for desire; therefore, they must have appetitive powers. Medieval philosophers distinguish between two kinds of appetite; a rational appetite, called the will, that is responsive to the dictates of the intellect, and an appetite that is responsive to sensory apprehension, called the sensory appetite. Since activities such as thinking and desiring are different sorts of activities, most theorists thought of their corresponding powers, the (practical) intellect and the will, as separate. However, on Philip's account, the practical intellect and the will are not separate powers. He argues that with respect to the capacity for performing actions, there is only one power with two separate acts. Philip gives a number of arguments for this position. One of them is particularly interesting because Philip uses the doctrine of the transcendentals to establish his conclusion that the practical intellect and will are one and the same power. Philip first notes that the intellect and the will have different ends. The intellect, even as practical intellect, has truth as its goal or end since its job, so to speak, is to ascertain the way things are, to make judgments about the state of reality, including what alternatives for action are available for the agent. The will, on the other hand, is an appetite for the good; it inclines the agent toward what she

judges to be good. Thus, its end is the good. But according to the doctrine of the transcendentals, the true and the good differ only intensionally, not extensionally. Philip thinks that if the ends of the powers do not differ extensionally, then the powers themselves do not differ extensionally as well. Thus, with respect to action, there is only one power with two different acts, acts of conceiving and judging on the one hand, and acts of desiring (the good) and willing on the other. Talking about the will is merely shorthand for referring to acts of willing or desiring. Talking about the intellect is merely shorthand for referring to certain cognitive judgments about what to do or how to act.

Although Philip denies that the practical intellect and the will are separate powers, he argues for a distinction among the various apprehensive powers. Thus, he sees a genuine distinction between the speculative intellect, the practical intellect, imagination, and the sensory apprehensive powers. This is because what is apprehended by each of these powers is different in nature. Philip denies that any such distinction is present among motive powers. Insofar as the appetite is moved by a sensory apprehension, we call it the sensory appetite. Insofar as the appetite is moved by the judgment of intellect, we call it the will. However, in reality, there is only one motive power to account for both of these sorts of desires, according to Philip. Philip's position on the inseparability of practical intellect and will does not appear to have convinced his thirteenth-century contemporaries or near-contemporaries. Albert the Great in *Summa de homine* (*circa* 1245) addresses the arguments given by Philip for his position although as was the custom of the time with respect to one's contemporaries or near-contemporaries, he does not refer to Philip by name. Albert rejects Philip's position, but the fact that Albert examines the issue at all indicates something about the esteem given to Philip's work.

An important part of thirteenth-century psychology was the development of a theory of free action. This was especially important both for theology and for ethics. Medieval thinkers, beginning with Augustine, recognized that moral responsibility requires freedom and so the possibility of that freedom needed to be explained. Along those same lines, they argued that unless human beings are able to act freely, God is not justified in punishing sins. Furthermore, human freedom plays a major role in theodicy; for example, Augustine argues that God is not responsible for the evil found in the world because that evil is perpetuated by the free choices of human beings. Thus, given this background and these commitments, it was common for medieval philosophers to examine the topic of freedom somewhere in their writings. In the first half of the thirteenth century, it was customary to examine these issues in the context of a treatise on what became known as *liberum arbitrium*. In medieval theories of action in the early part of the thirteenth century, "*liberum arbitrium*" is a technical term. It is a placeholder for whatever it is that enables human beings to act freely. The term originates in the work of Augustine who wrote a treatise entitled *De libero arbitrio*. The starting point for thirteenth-century treatises on *liberum arbitrium* was a definition taken from Peter Lombard's *Sentences*: "*liberum arbitrium* is a faculty of reason and will, by which good is chosen with the assistance of grace, or evil, when grace is not there to assist. And it is called '*liberum*' with respect to the will, which can be turned toward either [good or bad], while [it is called] '*arbitrium*' with respect to reason, as it has to do with that power or faculty to which the discerning between good and evil belongs." Although Lombard's main discussion of *liberum arbitrium* is found in book two, distinction twenty-five of his *Sententiae in IV libris distinctae*, this definition is found in the twenty-fourth distinction of book two, chapter three. This definition was commonly but mistakenly attributed to Augustine by commentators in the thirteenth century. Lombard himself does not reveal his

source. References to Augustine dominate his discussion of *liberum arbitrium* which might account for the association of the definition with Augustine.

Philosophers in the early thirteenth century faced the task of how to understand this definition. Although it is obvious from Lombard's formulation that both intellect and will have something to do with *liberum arbitrium*, their exact relationship is unclear. The phrase "*liberum arbitrium*" itself contributes to the uncertainty. The first part of the phrase, "*liberum*," is uncontroversial; it simply means "free." Difficulties arise with respect to the notion of "*arbitrium*." This notion has both cognitive and appetitive connotations, for it can have meanings as diverse as "judgment," "decision," "wish," or "inclination." It can also refer to a power or ability to make judgments or decisions or to the very agent who makes these judgments or decisions. Thus, the term covers a lot of territory, territory that has to do with both cognitive and appetitive capabilities. Accordingly, it is natural to connect *liberum arbitrium* with both intellect and will. In writing treatises on *liberum arbitrium*, thirteenth-century philosophers sought to sort out the connections between intellect and will on the one hand and the production and freedom of human action on the other. Some of these philosophers argued that free action results from the interaction of intellect and will, while others argued that although the intellect is an important precondition for an action's being free, the will is the true instrument that brings about a free action. Still others argued that *liberum arbitrium* is a separate faculty altogether although it is closely linked with and interacts with the intellect and will in the production of a free action. The practice of writing treatises on *liberum arbitrium* began to die off toward the later decades of the thirteenth century when philosophers started examining the topic of *voluntas libera* (free will) instead.

In his treatise on *liberum arbitrium* in *Summa de bono*, Philip adopts John Damascene's basic description of action. According to Damascene, an eighth-century patristic, a number of different stages come together in the production of an action. These stages include desiring, considering the various courses of action which will satisfy one's desires, deliberating over those courses of action, judging which one is to be performed, willing and choosing a particular alternative, and initiating the action. Since each of these activities are activities of the will and of the intellect, it follows that actions result from the activities of the will and the intellect. Damascene also claims that each of these stages are performed freely. Because each stage is performed freely, the resulting action is also free.

Philip modifies this position. He thinks that only the final activity of the intellect is performed freely, that is, the final judgment about what course of action to take. This is because Philip thinks that with respect to the previous activities of the intellect, activities such as identifying possible courses of action and deliberating over them, the intellect suffers from certain constraints. These constraints have to do with the structure of the world around us which in turn structures our beliefs. Beliefs play a role in our deliberations over what to do; thus the constraints placed upon beliefs in turn constrain the intellect in its activities. But according to Philip, the intellect retains some freedom for the final judgment about what to do is made freely. Thus, the intellect need not judge that a particular course of action be performed; it could have judged differently. In Philip's view, the will does not suffer from such constraints. The will is an appetite for the good so that whatever it wills, it wills a good. But a thing's being a good is merely a necessary condition, not a sufficient one. A thing's being good does not compel the will's act. Moreover, no judgment of the intellect constrains the will's choice; the will is free either to will the alternative put

forth by the intellect or to reject it and will something else. It is because of this capacity of the will that Philip sees the will as the primary source of freedom in a human being. For in the final analysis, it is the will rather than the judgment of the intellect that determines the action the agent performs. Because the will wills freely, the agent performs the action freely. Thus, while both intellect and will have important roles to play in the production of a free action, freedom is primarily a function of the will. Philip's theory of action helps to set the stage for the prominent voluntarist movement that rose later in the thirteenth century with thinkers such as Peter John Olivi and John Duns Scotus.

Artifact

An artifact may be defined as an object that has been intentionally made or produced for a certain purpose. Often the word ‘artifact’ is used in a more restricted sense to refer to simple, hand-made objects (for example, tools) which represent a particular culture. (This might be termed the ‘archaeological sense’ of the word.) In experimental science, the expression ‘artifact’ is sometimes used to refer to experimental results which are not manifestations of the natural phenomena under investigation, but are due to the particular experimental arrangement.

Artifacts

Artifacts are contrasted to natural objects; they are products of human actions. Consequently an artifact has necessarily a maker or an author. Using the word ‘author’ in a somewhat generalized sense, we may thus adopt the principle:

> (A1) If an object is an artifact, it has an author.

Can (A1) be strengthened to an equivalence? Experimental artifacts are unintended products of the experimenter's plans and actions, but otherwise the word is usually applied only to intended products: not all products of an agent's actions are artifacts. If we restrict the application of the expressions ‘author’ and ‘authorship’ in a similar way, we might strengthen (A1) to

> (A2) An object is an artifact if and only if it has an author.

According to (A2), *artifact* and *author* are correlative concepts (Hilpinen 1993). It should be observed

that (A2) allows the possibility that an artifact has more than one author: such objects may be termed ‘collective artifacts’. (A2) makes the concept of artifact equivalent to that of *work* (as product as opposed to activity); for example, according to (A2), all works of art, including musical and literary works, should be called ‘artifacts’ insofar as they have authors. In aesthetics, the expression ‘artifact’ has been used in this wide sense when it has been argued, as many philosophers have done, that works of art are necessarily artifacts. In a more restricted sense which is closer to the "archaeological" meaning mentioned above, artifacts are physical objects or in any case inhabitants of the physical, spatio-temporal world. If we say that an author can create a work only by making some artifact (e.g., to write a novel, one has to produce a manuscript), the expression ‘artifact’ is used in this narrow (or primary) sense.

An object which is an artifact in this primary sense is usually made from some pre-existing object or objects by successive intentional modifications; this activity is called *work*. This feature of artifacts is reflected in the definition of an artifact as an object "showing human workmanship or modification".

When a person intends to make an object, his productive intention has as its content some description of the intended object; the agent intends to make an object of a certain kind. An author's intention "ties" to an artifact a number of predicates which determine the *intended character* of the object. The existence and some of the properties of the artifact are dependent on its intended character. This is expressed by the following *Dependence Condition*:

> (DEP) The existence and some of the properties of an artifact depend on an agent's (or author's) intention to make an object of certain kind.

The causal tie between an artifact and its intended character -- or, strictly speaking, between an artifact and the author's productive intention -- is mediated by the author's actions, that is, by his work on the object. The actual properties of an artifact constitute its *actual character*. The success of the author's productive activity depends on the degree of fit or agreement between the intended and the actual character of the object. The actual character of an artifact is of course always much richer than the intended character; the artifact fits the author's intentions if and only if the former includes the latter. At least one of the descriptions included in the intended character must be a sortal predicate which determines the identity of the object and the criteria by which it can be distinguished from other objects. For example, ‘painting’ and ‘chair’ are sortal descriptions, but ‘red thing’ is not: it is possible to give a definite answer to the question of how many chairs there are in a given room, but not to the question of how many red things there are in the room.

The Evaluation of Artifacts

Often an artifact is identified by a sortal description which refers to its intended function (e.g., ‘hammer’). But this need not always be the case: for example, ‘painting’ is an artifact sortal which is not derived from the purpose or function of the object, but from the way in which it has been produced. An object that has been made for a purpose *F* may be termed ‘an *F*-object’. The properties of an *F*-object can be divided into two classes: (i) those relevant to the functioning of the object as an *F*-object, and (ii) the

properties irrelevant to the purpose *F*. The former properties may be termed the *significant* properties of the object (or its *F-significant* properties); they may also be called the "good-making properties" of the object. For example, the weight of a hammer is one of its significant features, but its color is not. In addition to an identifying (sortal) description *F*, the content of an author's productive intention includes the properties that he regards as significant for the purpose *F*. The latter properties depend on this purpose (or purposes); thus the intended character of an artifact is not simply a collection of predicates, but has a hierarchical structure. In many cases an object is expected to serve many different purposes; thus the description *F* may be quite complex.

An author's productive activity may be *evaluated* on the basis of the relationships among the intended character of an artifact, its actual character, and a purpose *F*:

> (E1) The degree of fit or agreement between the intended character and the actual character of an object,

> (E2) The degree of fit between the intended character of an object and the purpose *F*, in other words, the suitability of an object of the intended kind for the purpose *F*,

and

> (E3) The degree of fit between the actual character of an object and the purpose *F*, that is, the suitability of an artifact for *F*.

(E1) determines whether an artifact is a successful embodiment of the author's intentions, (E2) determines whether the character that the author intends to give to an artifact is suitable for the purpose *F*, and (E3) tells whether the author has succeeded in making an object that is in fact suitable for the purpose *F*. The study of artifacts (*as* artifacts) is intrinsically evaluative, since viewing an object as an artifact means viewing it in the light of intentions and purposes.

The purpose *F* on which the evaluation of an artifact and its design is based need not be the purpose that the author had in mind; it can be any purpose for which the artifact might be used. The direction of evaluation may be reversed so that the maker or owner of an artifact tries to find new uses for it. In addition, we should distinguish the actual character of an artifact from the author's conception of it. If the author's conception of an object agrees with its intended character, the artifact is subjectively satisfactory for the author, but it may fail to fit the author's productive intentions if he has a mistaken conception of it.

If the author's productive activity is successful, the character of a completed artifact both depends on and agrees with his productive intentions so that it can be regarded as an embodiment of these intentions.If the actual character of an object does not agree with its intended character, it is unsatisfactory from the author's point of view, and if the author's conception of an object does not agree with its intended character, the artifact is subjectively unsatisfactory from the author's point of view. In the latter case the

author has a reason to try to improve the object until it satisfies his productive intentions. A change in an object which improves the fit between its actual and intended character is, from the standpoint of the author's intentions, a *progressive* change.

It seems plausible to regard an object as a proper artifact only if its maker's productive activity has some degree of success, for example, satisfies some sortal predicate included in his productive intention. This condition may be termed the *Success Condition*:

> (SUC) An object is an artifact made by an author only if it satisfies some sortal description included in the author's productive intention.

If an agent's activity fails in every respect, the agent does not accomplish anything, but produces only "scrap". But even if the object does not fit the author's productive intention, but he *accepts* it as a satisfactory realization of his intention, it may be regarded as a proper artifact; this is expressed by the following *Acceptance Condition*:

> (ACC) An object is an artifact made by an author only if the author accepts it as satisfying some sortal description included in his productive intention.

If an artifact has several authors, the Acceptance Condition should hold for at least one of them. According to the Acceptance Condition, an object is an artifact only if its maker regards it as such, that is, accepts it as a product of his intentional activity. The Success Condition concerns the fit between the actual and the intended character of an object; the Acceptance Condition the fit between the author's conception of an object and its intended character. In this context it should be observed that the author's intention may change during his productive activity. In the above conditions, ‘productive intention’ should be regarded as referring to the content of the author's "final" intentions concerning the artifact.

The conditions listed above provide a partial characterization of the concept of artifact. We might say that different intentionally modified objects exhibit different degrees of artifactuality, depending on how well they satisfy these conditions.

Randall Dipert's (1993) theory of artifacts includes the condition that an artifact (in the strict sense) should be intended by its author to be recognized as having been intentionally modified for a certain purpose. This is a plausible condition, since an *F*-object can presumably be a good *F*-object only if its potential users recognize it as such. However, this recognizability should not be taken to mean general recognizability: a mechanical shark used in making an adventure film is an artifact, but its authors do not wish the audience to recognize it as such, on the contrary; the condition of recognizability concerns only the persons who are using it in the making of the film.

Works of Art

As was mentioned above, artifactuality is often regarded as a defining characteristic of works of art (Stephen Davies 1991); for example, this is an essential condition in George Dickie's (1984) analysis, according to which a work of art is an "artifact of a kind created to be presented to an Artworld public". The condition of artifactuality is plausible only if the concept of artifact is understood in a wide sense in which intentionally created events and processes (e.g., performances) and works which have instances (for example, musical and literary works) can be regarded as artifacts. According to condition (A2), the condition of artifactuality in this sense is equivalent to the requirement that a work of art should have an author. Some philosophers of art have rejected the condition of artifactuality, using instances of "driftwood art" and analogous examples as counterexamples. According to condition (A2), this view has the seemingly paradoxical consequence that a work of art need not be a product of anyone's work and need not have an author. Other philosophers have responded to such examples by extending the concept of artifactuality in such a way that the presentation of a natural object as an object of aesthetic appreciation counts as an "intentional modification" required for artifactuality. If the expression ‘artifact’ is used in a sufficiently wide sense, the condition of artifactuality clearly holds for artworks, but it is equally obvious that not all works of art (or works in general) are artifacts in the narrow sense of the word. In aesthetic evaluation and criticism, however, they are treated as if they were artifacts.

Indispensability Arguments in the Philosophy of Mathematics

One of the most intriguing features of mathematics is its applicability to empirical science. Every branch of science draws upon large and often diverse portions of mathematics, from the use of Hilbert spaces in quantum mechanics to the use of differential geometry in general relativity. It's not just the physical sciences that avail themselves of the services of mathematics either. Biology, for instance, makes extensive use of difference equations and statistics. The roles mathematics plays in these theories is also varied. Not only does mathematics help with empirical predictions, it allows elegant and economical statement of many theories. Indeed, so important is the language of mathematics to science, that it is hard to imagine how theories such as quantum mechanics and general relativity could even be stated without employing a substantial amount of mathematics.

From the rather remarkable but seemingly uncontroversial fact that mathematics is indispensable to science, some philosophers have drawn serious metaphysical conclusions. In particular, Quine (1976; 1980a; 1980b; 1981a; 1981c) and Putnam (1979a; 1979b) have argued that the indispensability of mathematics to empirical science gives us good reason to believe in the existence of mathematical entities. According to this line of argument, reference to (or quantification over) mathematical entities such as sets, numbers, functions and such is indispensable to our best scientific theories, and so we ought to be committed to the existence of these mathematical entities. To do otherwise is to be guilty of what Putnam has called "intellectual dishonesty" (Putnam 1979b, p. 347). Moreover, mathematical entities are seen to be on an epistemic par with the other theoretical entities of science, since belief in the existence of the former is justified by the same evidence that confirms the theory as a whole (and hence belief in the latter). This argument is known as the Quine-Putnam indispensability argument for mathematical realism. There are other indispensability arguments,[1] but this one is by far the most influential, and so in what follows I'll concentrate on it.

Spelling Out the Quine-Putnam Indispensability Argument

The Quine-Putnam indispensability argument has attracted a great deal of attention, in part because many see it as the best argument for mathematical realism (or platonism). Thus anti-realists about mathematical entities (or nominalists) need to identify where the Quine-Putnam argument goes wrong. Many platonists, on the other hand, rely very heavily on this argument to justify their belief in mathematical entities. The argument places nominalists who wish to be realist about other theoretical entities of science (quarks, electrons, black holes and such) in a particularly difficult position. For typically they accept something quite like the Quine-Putnam argument[2]) as justification for realism about quarks and black holes. (This is what Quine (1980b, p. 45) calls holding a "double standard" with regard to ontology.)

For future reference I'll state the Quine-Putnam indispensability argument in the following explicit form:

> (P1) We ought to have ontological commitment to all and only the entities that are indispensable to our best scientific theories.
>
> (P2) Mathematical entities are indispensable to our best scientific theories.
>
> (C) We ought to have ontological commitment to mathematical entities.

Thus formulated, the argument is valid. This forces the focus onto the two premises. In particular, a couple of important questions naturally arise. The first concerns how we are to understand the claim that mathematics is indispensable. I address this in the next section. The second question concerns the first premise. It is nowhere near as self-evident as the second and it clearly needs some defense. I'll discuss its defense in the following section. I'll then present some of the more important objections to the argument, before considering the Quine-Putnam argument's role in the larger scheme of things - where it stands in relation to other influential arguments for and against mathematical realism.

What is it to be Indispensable?

The question of how we should understand 'indispensability' in the present context is crucial to the Quine-Putnam argument, and yet it has received surprisingly little attention. Quine actually speaks in terms of the entities quantified over in the canonical form of our best scientific theories rather than indispensability. Still, the debate continues in terms of indispensability, so we would be well served to clarify this term.

The first thing to note is that 'dispensability' is not the same as 'eliminability'. If this were not so, *every* entity would be dispensable (due to a theorem of Craig).[3] What we require for an entity to be 'dispensable' is for it to be eliminable *and* that the theory resulting from the entity's elimination be an attractive theory. (Perhaps, even stronger, we require that the resulting theory be *more* attractive than the original.) We will need to spell out what counts as an attractive theory but for this we can appeal to the standard desiderata for good scientific theories: empirical success; unificatory power; simplicity; explanatory power; fertility and so on. Of course there will be debate over what desiderata are appropriate and over their relative weightings, but such issues need to be addressed and resolved independently of issues of indispensability. (See Burgess (1983) and Colyvan (1999b) for more on these issues.)

These issues naturally prompt the question of *how much* mathematics is indispensable (and hence how much mathematics carries ontological commitment). It seems that the indispensability argument only justifies belief in enough mathematics to serve the needs of science. Thus we find Putnam speaking of "the set theoretic 'needs' of physics" (Putnam 1979b, p. 346) and Quine claiming that the higher reaches of set theory are "mathematical recreation ... without ontological rights" (Quine 1986, p. 400) since they do not find physical applications. One could take a less restrictive line and claim that the higher reaches of set theory, although without physical applications, do carry ontological commitment by virtue of the fact that they have applications *in other parts of mathematics*. So long as the chain of applications eventually "bottoms out" in physical science, we could rightfully claim that the whole chain carries ontological commitment. Quine himself justifies some transfinite set theory along these lines (Quine 1984, p. 788), but he sees no reason to go beyond the constructible sets (Quine 1986, p. 400). His reasons for this restriction, however, have little to do with the indispensability argument and so supporters of this argument need not side with Quine on this issue.

Naturalism and Holism

Although both premises of the Quine-Putnam indispensability argument have been questioned, it's the first premise that is most obviously in need of support. This support comes from the doctrines of naturalism and holism.

Following Quine, naturalism is usually taken to be the philosophical doctrine that there is no first philosophy and that the philosophical enterprise is continuous with the scientific enterprise (Quine 1981b). By this Quine means that philosophy is neither prior to nor privileged over science. What is more, science, thus construed (i.e. with philosophy as a continuous part) is taken to be the complete story of the world. This doctrine arises out of a deep respect for scientific methodology and an acknowledgment of the undeniable success of this methodology as a way of answering fundamental questions about all nature of things. As Quine suggests, its source lies in "unregenerate realism, the robust state of mind of the natural scientist who has never felt any qualms beyond the negotiable uncertainties internal to science" (Quine 1981b, p.72). For the metaphysician this means looking to our best scientific theories to determine what exists, or, perhaps more accurately, what we ought to believe to

exist. In short, naturalism rules out unscientific ways of determining what exists. For example, naturalism rules out believing in the transmigration of souls for mystical reasons. Naturalism would not, however, rule out the transmigration of souls if our best scientific theories were to require the truth of this doctrine.[4]

Naturalism, then, gives us a reason for believing in the entities in our best scientific theories and no other entities. Depending on exactly how you conceive of naturalism, it may or may not tell you whether to believe in *all* the entities of your best scientific theories. I take it that naturalism does give us *some* reason to believe in all such entities, but that this is defeasible. This is where holism comes to the fore: in particular, confirmational holism.

Confirmational holism is the view that theories are confirmed or disconfirmed as wholes (Quine 1980b, p. 41). So, if a theory is *confirmed* by empirical findings, the *whole* theory is confirmed. In particular, whatever mathematics is made use of in the theory is also confirmed (Quine 1976, pp. 120-122). Furthermore, as Putnam (1979a) has stressed, it is the same evidence that is appealed to in justifying belief in the mathematical components of the theory that is appealed to in justifying the empirical portion of the theory (if indeed the empirical can be separated from the mathematical at all). Naturalism and holism taken together then justify P1. Roughly, naturalism gives us the "only" and holism gives us the "all" in P1.

It is worth noting that in Quine's writings there are at least two holist themes. The first is the confirmational holism discussed above (often called the Quine-Duhem thesis). The other is semantic holism which is the view that the unit of meaning is not the single sentence, but systems of sentences (and in some extreme cases the whole of language). This latter holism is closely related to Quine's well-known denial of the analytic-synthetic distinction (Quine 1980b) and his equally famous indeterminacy of translation thesis (Quine 1960). Although for Quine, semantic holism and confirmational holism are closely related, there is good reason to distinguish them, since the former is generally thought to be highly controversial while the latter is considered relatively uncontroversial.

Why this is important to the present debate is that Quine explicitly invokes the controversial semantic holism in support of the indispensability argument (Quine 1980b, pp. 45-46). Most commentators, however, are of the view that only confirmational holism is required to make the indispensability argument fly (see, for example, Colyvan (1998); Field (1989, pp. 14-20); Hellman (199?); Resnik (1995a; 1997); Maddy (1992)) and my presentation here follows that accepted wisdom. It should be kept in mind, however, that while the argument, thus construed, is Quinean in flavor it is not, strictly speaking, Quine's argument.

Objections

There have been many objections to the indispensability argument, including Charles Parsons' (1980) concern that the obviousness of basic mathematical statements is left unaccounted for by the Quinean

picture and Philip Kitcher's (1984, pp. 104-105) worry that the indispensability argument doesn't explain *why* mathematics is indispensable to science. The objections that have received the most attention, however, are those due to Hartry Field, Penelope Maddy and Elliott Sober. In particular, Field's nominalisation program has dominated recent discussions of the ontology of mathematics.

Field (1980) presents a case for denying the second premise of the Quine-Putnam argument. That is, he suggests that despite appearances mathematics is not indispensable to science. There are two parts to Field's project. The first is to argue that mathematical theories don't have to be true to be useful in applications, they need merely to be *conservative*. (This is, roughly, that if a mathematical theory is added to a nominalist scientific theory, no nominalist consequences follow that wouldn't follow from the nominalist scientific theory alone.) This explains why mathematics *can* be used in science but it does not explain why it *is* used. The latter is due to the fact that mathematics makes calculation and statement of various theories much simpler. Thus, for Field, the utility of mathematics is merely pragmatic - mathematics is not indispensable after all.

The second part of Field's program is to demonstrate that our best scientific theories can be suitably nominalised. That is, he attempts to show that we could do without quantification over mathematical entities and that what we would be left with would be reasonably attractive theories. To this end he is content to nominalise a large fragment of Newtonian gravitational theory. Although this is a far cry from showing that *all* our current best scientific theories can be nominalised, it is certainly not trivial. The hope is that once one sees how the elimination of reference to mathematical entities can be achieved for a typical physical theory, it will seem plausible that the project could be completed for the rest of science.[5]

There has been a great deal of debate over the likelihood of the success of Field's program but few have doubted its significance. Recently, however, Penelope Maddy, has pointed out that if P1 is false, Field's project may turn out to be irrelevant to the realism/anti-realism debate in mathematics.

Maddy presents some serious objections to the first premise of the indispensability argument (Maddy 1992; 1995; 1997). In particular, she suggests that we ought not have ontological commitment to *all* the entities indispensable to our best scientific theories. Her objections draw attention to problems of reconciling naturalism with confirmational holism. In particular, she points out how a holistic view of scientific theories has problems explaining the legitimacy of certain aspects of scientific and mathematical practices. Practices which, presumably, ought to be legitimate given the high regard for scientific practice that naturalism recommends. It is important to appreciate that her objections, for the most part, are concerned with methodological consequences of accepting the Quinean doctrines of naturalism and holism - the doctrines used to support the first premise. The first premise is thus called into question by undermining its support.

Maddy's first objection to the indispensability argument is that the actual attitudes of working scientists towards the components of well-confirmed theories vary from belief, through tolerance, to outright rejection (Maddy 1992, p. 280). The point is that naturalism counsels us to respect the methods of

working scientists, and yet holism is apparently telling us that working scientists ought not have such differential support to the entities in their theories. Maddy suggests that we should side with naturalism and not holism here. Thus we should endorse the attitudes of working scientists who apparently do not believe in *all* the entities posited by our best theories. We should thus reject P1.

The next problem follows from the first. Once one rejects the picture of scientific theories as homogeneous units, the question arises whether the mathematical portions of theories fall within the true elements of the confirmed theories or within the idealized elements. Maddy suggests the latter. Her reason for this is that scientists themselves do not seem to take the indispensable application of a mathematical theory to be an indication of the truth of the mathematics in question. For example, the false assumption that water is infinitely deep is often invoked in the analysis of water waves, or the assumption that matter is continuous is commonly made in fluid dynamics (Maddy 1992, pp. 281-282). Such cases indicate that scientists will invoke whatever mathematics is required to get the job done, without regard to the truth of the mathematical theory in question (Maddy 1995, p. 255). Again it seems that confirmational holism is in conflict with actual scientific practice, and hence with naturalism. And again Maddy sides with naturalism. (See also Parsons (1983) for some related worries about Quinean holism.) The point here is that if naturalism counsels us to side with the attitudes of working scientists on such matters, then it seems that we ought not take the indispensability of some mathematical theory in a physical application as an indication of the truth of the mathematical theory. Furthermore, since we have no reason to believe that the mathematical theory in question is true, we have no reason to believe that the entities posited by the (mathematical) theory are real. So once again we ought to reject P1.

Maddy's third objection is that it is hard to make sense of what working mathematicians are doing when they try to settle independent questions. These are questions, that are independent of the standard axioms of set theory - the ZFC axioms.[6] In order to settle some of these questions, new axiom candidates have been proposed to supplement ZFC, and arguments have been advanced in support of these candidates. The problem is that the arguments advanced seem to have nothing to do with applications in physical science: they are typically intra-mathematical arguments. According to indispensability theory, however, the new axioms should be assessed on how well they cohere with our current best scientific theories. That is, set theorists should be assessing the new axiom candidates with one eye on the latest developments in physics. Given that set theorists do not do this, confirmational holism again seems to be advocating a revision of standard mathematical practice, and this too, claims Maddy, is at odds with naturalism (Maddy 1992, pp. 286-289).

Although Maddy does not formulate this objection in a way that directly conflicts with P1 it certainly illustrates a tension between naturalism and confirmational holism.[7] And since both these are required to support P1, the objection indirectly casts doubt on P1. Maddy, however, endorses naturalism and so takes the objection to demonstrate that confirmational holism is false. I'll leave the discussion of the impact the rejection of confirmational holism would have on the indispensability argument until after I outline Sober's objection, because Sober arrives at much the same conclusion.

Elliott Sober's objection is closely related to Maddy's second and third objections. Sober (1993) takes

issue with the claim that mathematical theories share the empirical support accrued by our best scientific theories. In essence, he argues that mathematical theories are not being tested in the same way as the clearly empirical theories of science. He points out that hypotheses are confirmed relative to competing hypotheses. Thus if mathematics is confirmed along with our best empirical hypotheses (as indispensability theory claims), there must be mathematics-free competitors. But Sober points out that *all* scientific theories employ a common mathematical core. Thus, since there are no competing hypotheses, it is a mistake to think that mathematics receives confirmational support from empirical evidence in the way other scientific hypotheses do.

This in itself does not constitute an objection to P1 of the indispensability argument, as Sober is quick to point out (Sober 1993, p. 53), although it does constitute an objection to Quine's overall view that mathematics is part of empirical science. As with Maddy's third objection, it gives us some cause to reject confirmational holism. The impact of these objections on P1 depends on how crucial you think confirmational holism is to that premise. Certainly much of the intuitive appeal of P1 is eroded if confirmational holism is rejected. In any case, to subscribe to the conclusion of the indispensability argument in the face of Sober's or Maddy's objections is to hold the position that it's permissible at least to have ontological commitment to entities that receive no empirical support. This, if not outright untenable, is certainly not in the spirit of the original Quine-Putnam argument.

Conclusion

It is not clear how damaging the above criticisms are to the indispensability argument. Indeed, the debate is very much alive, with many recent articles devoted to the topic. (See bibliography notes below.) Closely related to this debate is the question of whether there are any other decent arguments for platonism. If, as some believe, the indispensability argument is the *only* argument for platonism worthy of consideration, then if it fails, platonism in the philosophy of mathematics seems bankrupt. Of relevance then is the status of other arguments for and against mathematical realism. In any case, it is worth noting that the indispensability argument is one of a small number of arguments that have dominated discussions of the ontology of mathematics. It is therefore important that this argument not be viewed in isolation.

The two most important arguments *against* mathematical realism are the epistemological problem for platonism - how do we come by knowledge of causally inert mathematical entities? (Benacerraf 1983b) - and the indeterminacy problem for the reduction of numbers to sets - if numbers are sets, which sets are they (Benacerraf 1983a)? Apart from the indispensability argument, the other major argument *for* mathematical realism is that it is desirable to provide a uniform semantics for *all* discourse: mathematical and non-mathematical alike (Benacerraf 1983b). Mathematical realism, of course, meets this challenge easily, since it explains the truth of mathematical statements in exactly the same way as in other domains.[8] It is not so clear, however, how nominalism can provide a uniform semantics.

Finally, it is worth stressing that even if the indispensability argument *is* the only good argument for platonism, the failure of this argument does not necessarily authorize nominalism, for the latter too may

be without support. It does seem fair to say, however, that if the objections to the indispensability argument are sustained then one of the most important arguments for platonism is undermined. This would leave platonism on rather shaky ground.[9]

Bibliography

Although the indispensability argument is to be found in many places in Quine's writings (including 1976; 1980a; 1980b; 1981a; 1981c), the *locus classicus* is Putnam's short monograph *Philosophy of Logic* (included as a chapter of the second edition of the third volume of his collected papers (Putnam, 1979b)). See also Putnam (1979a) and the introduction of Field (1989) which has an excellent outline of the argument. Colyvan (2001) is a sustained defence of the argument.

See Chihara (1973), and Field (1980; 1989) for attacks on the second premise and Colyvan (1999b; 2001), Maddy (1990), Malament (1982), Resnik (1985), Shapiro (1983) and Urquhart (1990) for criticisms of Field's program. For a fairly comprehensive look at nominalist strategies in the philosophy of mathematics (including a good discussion of Field's program), see Burgess and Rosen (1997), while Feferman (1993) questions the amount of mathematics required for empirical science. See Azzouni (1997), Balaguer (1996b; 1998), Maddy (1992; 1995; 1997), Melia (2000), Peressini (1997), Sober (1993) and Vineberg (1996) for attacks on the first premise. Colyvan (1998; 1999a; 2001; 2002), Hellman (1999) and Resnik (1995a; 1997) reply to some of these objections.

For variants of the Quinean indispensability argument see Maddy (1992) and Resnik (1995a).

Notes to Indispensability Arguments in the Philosophy of Mathematics

---

Notes

1. In general, an indispensability argument is an argument that purports to establish the truth of some claim based on the indispensability of the claim in question for certain purposes (to be specified by the particular argument). For example, if *explanation* is specified as the purpose, then we have an explanatory indispensability argument. Thus we see that inference to the best explanation is a special case of an indispensability argument. See the introduction of Field (1989, pp. 14-20) for a nice discussion of indispensability arguments and inference to the best explanation. See also Maddy (1992) and Resnik 1995a) for variations on the Quine-Putnam version of the argument.

2. Most scientific realists accept inference to the best explanation. Indeed, it might be said that inference to the best explanation is the cornerstone of scientific realism. But, as we saw in note 1, inference to the best explanation may be seen as a kind of indispensability argument, so any realist who accepts the former while rejecting the latter is in a somewhat delicate position.

3. This theorem states that relative to a partition of the vocabulary of an axiomatizable theory *T* into two classes, *t* and *o* (theoretical and observational, say) there exists an axiomatizable theory *T** in the language whose only non-logical vocabulary is *o*, of all and only the consequences of *T* that are expressible in *o* alone. If the vocabulary of the theory can be partitioned in the way that Craig's theorem requires, then the theory can be reaxiomatized so that apparent reference to any given theoretical entity is eliminated. See Field (1980, p. 8) for further details.

4. It turns out that the details of the formulation of naturalism are crucial to the argument. See Maddy (1998) for a slightly different formulation that doesn't support the conclusion of the Quine-Putnam argument.

5. The issue of how likely modern theories such as general relativity and quantum mechanics are to yield to nominalisation is a very interesting and controversial matter. David Malament (1982) argues that quantum mechanics, for one, is likely to resist nominalisation because of the central role infinite-dimensional Hilbert spaces play in the theory. Mark Balaguer (1996a; 1998), however, suggests a way of nominalising the Hilbert spaces in question.

6. For example, the continuum hypothesis is the assertion that the cardinality of the real numbers is the first non-denumerable cardinal. It turns out that neither this hypothesis nor its negation is provable from the ZFC axioms; the question of the size of the continuum is *independent* of ZFC.

7. It is tempting to formulate Maddy's third objection as follows:

> Naturalism endorses actual mathematical practice. This practice typically does not rely on extra-mathematical canons of justification. So it seems that naturalism endorses belief in some mathematical theories with or without finding physical applications for them. Presumably this belief carries with it certain ontological commitments. So it seems that we ought to have ontological commitment to at least some entities that are not indispensable to our best (empirical) theories. Thus it might be argued that a thoroughgoing naturalist is not committed to *only* the entities of our best scientific theories and thus is not committed to P1.

This, however, I think is to misrepresent Maddy's argument. For starters, the indispensability argument can be made to work with P1 reading: 'We ought to have ontological commitment to all the entities that are indispensable to our best scientific theories'. That is, the 'only' part argued against in the above formulation of Maddy's objection is unnecessary. More importantly, I think that Maddy's objection is subtler than this formulation. The objection is directed at the motivation for P1 - not at P1 itself. Her aim is to show that confirmational holism ought to be rejected. This would rob P1 of much of its plausibility, as we shall see in the discussion following that dealing with Sober's objection.

8. For example, 'There is a city larger than Hobart' and 'There is a natural number larger than 100' are true just in case there exist objects in the respective domains of quantification with the properties of being larger than Hobart and being larger than the natural number 100 respectively. Such a strategy is not open to anyone who holds that (i) both these sentences are true, (ii) numbers do not exist and (iii) cities do exist. Most nominalists thus find themselves unable to employ such a semantics. Field is a notable exception here (Field, 1980; 1989); he denies that sentences such as 'There is a natural number larger than 100' are true. He claims that they are *true-in-the-story-of-mathematics* but that this is not true *simpliciter*. He thus avoids the difficult problem of providing a nominalisticlly acceptable account of the truth of such sentences. (He does, however, have a residual worry. According to Field, sentences such as 'In Peano number theory there is a number larger than 100' *are* true *simpliciter*, but it's not clear that he has a fully-developed semantics for these.)

9. I'd like to thank Helen Regan, Angela Rosier and Ed Zalta for comments on earlier versions of this entry.

Thought Experiments

Thought experiments are devices of the imagination used to investigate nature. We need only list a few of the well-known thought experiments to be reminded of their enormous influence and importance in the sciences: Newton's bucket, Maxwell's demon, Einstein's elevator, Heisenberg's gamma-ray microscope, Schrödinger's cat. The 17th century saw some of its most brilliant practitioners in Galileo, Descartes, Newton, and Leibniz. And in our own time, the creation of quantum mechanics and relativity are almost unthinkable without the crucial role played by thought experiments. Galileo and Einstein were, arguably, the most impressive thought experimenters, but they were by no means the first. Thought experiments existed throughout the middle ages, and can be found in antiquity, too.

Examples of Thought Experiments

One of the most beautiful early examples (Lucretius, *De Rerum Natura*) attempts to show that space is infinite: If there is a boundary to the universe, we can toss a spear at it. If the spear flies through, it isn't a boundary after all; if the spear bounces back, then there must be something beyond the supposed edge of space, a cosmic wall which is itself in space that stopped the spear. Either way, there is no edge of the universe; space is infinite. This example nicely illustrates many of the common features of thought experiments: We visualize some situation; we carry out an operation; we see what happens. It also illustrates their fallibility. (In this case we've learned how to conceptualize space so that it is both finite and unbounded.)

Often a real experiment that is the analogue of a thought experiment is impossible for physical, technological, or just plain practical reasons; but this needn't be a defining condition of thought experiments. The main point is that we seem able to get a grip on nature just by thinking, and therein lies the great interest for philosophy. How is it possible to learn (apparently) new things about nature without new empirical data?

Ernst Mach (who seems to have coined the expression *Gedankenexperiment*) developed an interesting empiricist view in his classic, *The Science of Mechanics*. We possess, he says, a great store of "instinctive knowledge" picked up from experience. This needn't be articulated at all, but comes to the fore when we consider certain situations. One of his favourite examples is due to Simon Stevin. When a chain is draped over a double frictionless plane, as in Fig. 1a, how will it move? Add some links as in Fig. 1b.

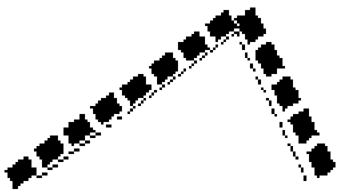

Figure 1a

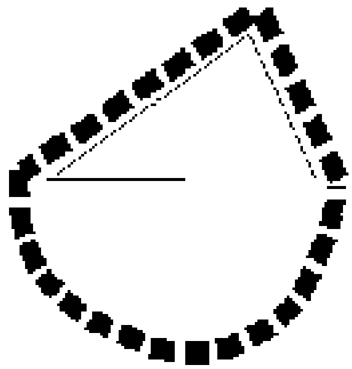

Figure 1b

Now it is obvious. The initial setup must have been in static equilibrium. Otherwise, we would have a perpetual motion machine; and according to our experience-based "instinctive knowledge", says Mach, this is impossible.

Recent Work on Thought Experiments

Thomas Kuhn's "A Function for Thought Experiments" employs many of the concepts (but not the terminology) of his well-known Structure of Scientific Revolutions. On his view a well-conceived thought experiment can bring on a crisis or at least create an anomaly in the reigning theory and so contribute to paradigm change. So thought experiments can teach us something new about the world, even though we have no new data, by helping us to reconceptualize the world in a better way.

Recent years have seen a sudden growth of interest in thought experiments. The views of Brown (1991) and Norton (1991, 1996) represent the extremes of platonic rationalism and classic empiricism, respectively. Norton claims that any thought experiment is really a (possibly disguised) argument; it starts with premisses grounded in experience and follows deductive or inductive rules of inference in arriving at its conclusion. The picturesque features of any thought experiment which give it an experimental flavour might be psychologically helpful, but are strictly redundant. Thus, says Norton, we never go beyond the empirical premisses in a way to which any empiricist would object. (For criticisms see Brown (1991, 1993) and for a defense see Norton (1996).)

By contrast, Brown holds that in a few special cases we do go well beyond the old data to acquire *a*

priori knowledge of nature. Galileo showed that all bodies fall at the same speed with a brilliant thought experiment that started by destroying the then reigning Aristotelian account. The latter holds that heavy bodies fall faster than light ones (H > L). But consider (Fig. 2), in which a heavy canon ball (H) and light musket ball (L) are attached together to form a compound object (H+L); the latter must fall faster than the cannon ball alone. Yet the compound object must also fall slower, since the light part will act as a drag on the heavy part. Now we have a contradiction. (H+L > H and H > H+L) That's the end of Aristotle's theory; but there is a bonus, since the right account is now obvious: they all fall at the same speed (H = L = H+L).

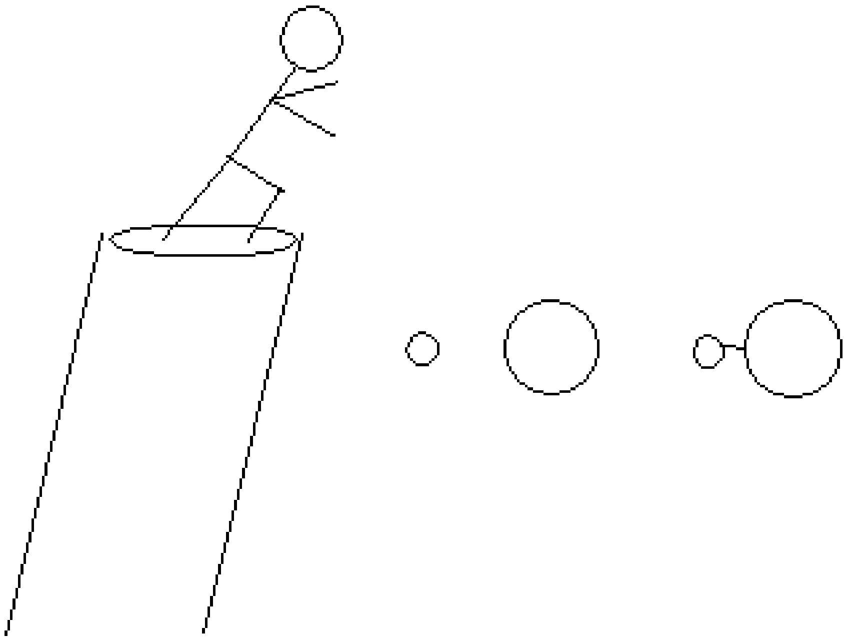

Figure 2

This is said to be *a priori* (though still fallible) knowledge of nature since there are no new data involved, nor is the conclusion derived from old data, nor is it some sort of logical truth. This account of thought experiments is further developed by linking the a priori epistemology to a recent account of laws of nature which holds that laws are relations between objectively existing abstract entities. It is thus a rather platonistic view, not unlike platonistic accounts of mathematics such as that urged by Gödel. (For details see Brown 1991.)

The two views just sketched might occupy the opposite ends of a spectrum of positions on thought experiments. Some of the promising new alternative views include those of Sorensen (somewhat in the spirit of Mach) who holds that thought experiments are a "limiting case" of ordinary experiments; they can achieve their aim, he says, without being executed. (Sorensen's book is also valuable for its extensive discussion of thought experiments in philosophy of mind, ethics, and other areas of philosophy, as well as the sciences.) Other promising views include those of Gooding (who stresses the similar procedural nature of thought experiments and real experiments), Miscevic and Nersessian (each of whom tie thought experiments to "mental models"), and several of the accounts in Horowitz and Massey (1991). More recent excellent discussions include: Arthur (1999), Gendler (1998), Haggqvist (1996), Humphreys

(1994), Genz (1999), McAllister (1996). The literature on thought experiments continues to grow rapidly.

Category Theory

Category theory is a general mathematical theory of structures and sytems of structures. It allows us to see, among other things, how structures of different kinds are related to one another as well as the universal components of a family of structures of a given kind. The theory is philosophically relevant in more than one way. For one thing, it is considered by many as being an alternative to set theory as a foundation for mathematics. Furthermore, it can be thought of as constituting a theory of concepts. Finally, it sheds a new light on many traditional philosophical questions, for instance on the nature of reference and truth.

General Definitions

Category theory is a generalized mathematical theory of structures. One of its goals is to reveal the universal properties of structures of a given kind via their relationships with one another. Formally, a category **C** can be described as a collection **Ob**, the *objects* of **C**, which satisfy the following conditions:

> For every pair *a*, *b* of objects, there is a collection **Mor**(*a*, *b*), namely, the morphisms from *a* to *b* in **C** (when **f** is a morphism from *a* to *b*, we write **f**: $a \rightarrow b$);
>
> For every triple *a*, *b* and *c* of objects, there is a partial operation from pairs of morphisms in **Mor**(*a*, *b*) X **Mor**(*b*, *c*) to morphisms in **Mor**(*a*, *c*), called the composition of morphisms in **C**
> (when **f**: $a \rightarrow b$ and **g**: $b \rightarrow c$, (**g** o **f**): $a \rightarrow c$ is their composition);
>
> For every object *a*, there is a morphism **id***a* in Mor(*a*, *a*), called the identity on *a*.

Furthermore, morphisms have to satisfy two axioms:

> Associativity: if **f**: $a \rightarrow b$, **g**: $b \rightarrow c$ and **h**: $c \rightarrow d$, then **h** o (**g** o **f**) = (**h** o **g**) o **f**
>
> Identity: if **f**: $a \rightarrow b$, then (**id***b* o **f**) = **f** and (**f** o **id***a*) = **f**.

One of the interesting features of category theory is that it provides a uniform treatment of the notion of structure. This can be seen, first, by considering the variety of examples of categories. Almost every known example of a mathematical structure with the appropriate structure preserving map yields a category. Thus, sets with functions between them constitute a category. Groups with group homomorphisms constitute a category. Topological spaces with continuous maps constitute a category. Vector spaces and linear maps constitute a category. Differential manifolds with smooth maps constitute a category. And so on. It is important to note that what characterizes a category is its morphisms and not its objects. Thus, the category of topological spaces with *open* maps is a different category than the category of topological spaces with continuous maps. In particular, the latter will have different properties as a category than the former. The previous examples have something in common: the objects are all structured sets with structure preserving maps. However, any entity satisfying the conditions given in the definition is a category. Thus, any preordered set is a category. For, given two elements *p*, *q* of the preordered set, there is a morphism **f**: $p \rightarrow q$ if and only if *p* is smaller or equal to *q*. Hence, a preordered set is a category in which there is at most one morphism between any two objects. A deductive system such that the entailment relation is reflexive and transitive is a category. Any monoid (and thus any group) can be seen as a category: in this case, the category has only one object and the morphisms of the category are given by the elements of the monoid. Composition of morphisms corresponds to multiplication of elements of the monoid. It is easily checked that the axioms of a monoid corresponds to the axioms of a category in this particular case. It can therefore be said that the notion of a category is a generalization of the concept of preorder *and at the same time* a generalization of the notion of monoid.

Category theory unifies mathematical structures in a second, perhaps even more important, manner. Once a type of structure has been defined, it quickly becomes imperative to determine how new structures can be constructed out of the given one and how given structures can be decomposed into more elementary substructures. For instance, given two sets A and B, set theory allows us to construct their cartesian product A X B. For an example of the second sort, given a finite abelian group, it can be decomposed into a product of some of its subgroups. In both cases, it is necessary to know how structures of a certain kind combine. The nature of these combinations might appear to be considerably different when looked at from too close. Category theory reveals that many of these constructions are in fact special cases of objects in a category with what is called a "universal property". Indeed, from a categorical point of view, a set-theoretical cartesian product, a direct product of groups, a direct product of abelian groups, a product of topological spaces and a conjunction of propositions in a deductive system are all instances of a categorical concept: the categorical product. What characterizes the latter is a universal property. Formally, a product for two objects *a* and *b* in a category **C** is an object *c* of **C** *together with* two morphisms, called the projections, **p**: $c \rightarrow a$ and **q**: $c \rightarrow b$ such that, and this is the universal property, for all object *d* with morphisms **f**: $d \rightarrow a$ and **g**: $d \rightarrow b$, there is a unique morphism **h**: $d \rightarrow c$ such that **p** o **h**

= **f** and **q** o **h** = **g**. Notice that we have defined a product for *a* and *b* and not the product for *a* and *b*. Indeed, products and, in fact, every object with a universal property, are defined up to (a unique) isomorphism. Thus, in category theory, the nature of the elements constituting a certain construction is irrelevant. What matters is the way an object is related to the other objects of the category, that is, the morphisms going in and the morphisms going out, or, put differently, how certain structures can be mapped into it and how it can map its structure into other structures of the same kind.

Another crucial aspect of category theory is that it allows to see how different kind of structures are related to one another. For instance, in algebraic topology, topological spaces are related to groups by various means (homology, cohomology, homotopy, K-theory). It was precisely in order to clarify how these connections are made and to compare them with one another that Eilenberg and Mac Lane invented category theory. Indeed, topological spaces with continuous maps constitute a category and similarly groups with group homomorphisms. In the very spirit of category theory, what should matter here are the morphisms between categories. These are given by functors and are informally structure preserving maps between categories. This simply means that, given two categories **C** and **D**, a functor F from **C** to **D**, should send objects of **C** to objects of **D** and morphisms of **C** to morphisms of **D** in such a way that composition of morphisms in **C** is preserved, i.e. F(**g** o **f**) = F(**g**) o F(**f**), and identity morphisms are preserved, i.e. F(**id***a*) = **id**F*a*. It follows immediately that a functor preserves commutativity of diagrams between categories. Homology, cohomology, homotopy, K-theory are all example of functors. A more direct example is provided by the power set operation which yields two functors on the category of sets, depending on how one defines its action on functions. Thus, given a set X, P(X) is the usual set of subsets of X and given a function f: X → Y, P(f): P(X) → P(Y) takes a subset A of X and maps it to B = f(A), the image of f restricted to A in Y. It is easily verified that it is a functor. There are in general many functors between two given categories and it becomes natural to ask how they are connected. For instance, given a category **C**, there is always the identity functor from **C** to **C** which sends every object of **C** to itself and every morphism of **C** to itself. In particular, there is the identity functor over the category of sets. Now, the identity functor is related to the power set functor described above in a natural manner. Indeed, given a set X and its power set P(X), there is a function hX which takes an element x of X and send it to the singleton set {x}, a subset of X, i.e. an element of P(X). This function in fact belongs to a family of functions indexed by the objects of the category of sets {hY: Y → P(Y)| Y in **Ob(Set)**}. Moreover, it satisfies the following commutativity condition. Given any function f: X → Y, the identity functor yields the same function Id(f): Id(X) → Id(Y). The commutativity condition thus becomes: hY o Id(f) = P(f) o hX. Thus the family of functions h(-) relates the two functors in a natural manner. Such families of morphisms are called *natural transformations* between functors.

The above notions constitute the elementary concepts of category theory. However it should be noted that they are not fundamental notions of category theory. These are arguably the notions of limits/colimits which are, in turn, special cases of what is certainly the cornerstone of the theory, the concept of adjoint functors. We will not present the definition here. Suffice it to say that adjoint functors pervade mathematics and this pervasiveness is certainly one of the most mysterious fact that category theory reveals about mathematics and probably thinking in general.

Brief Historical Sketch

It is difficult to do justice to the short but intricate history of the field, in particular it is not possible to mention all those who have contributed to its rapid development. This warning being said, here are some of the main threads that have to be mentioned.

Categories, functors, natural transformations, limits and colimits appeared almost out of nowhere in 1945 in Eilenberg & Mac Lane's paper entitled "General Theory of Natural Equivalences". We said "almost", because when one looks at their 1942 paper "Group Extensions and Homology", one discovers specific functors and natural transformations at work. In fact, it was basically the need to clarify and abstract from their 1942 results that Eilenberg & Mac Lane came up with the notions of category theory. The central notion for them, as the title indicates, was the notion of natural transformation. In order to give a general definition of the latter, they defined the notion of functor, borrowing the terminology from Carnap, and in order to give a general definition of functor, they defined the notion of category, borrowing this time from Kant and Aristotle. After their 1945 paper, it was not clear that the concepts of category theory would be more than a convenient language. Then in 1950, Mac Lane used the language of categories to give an arrow theoretic definition of the notion of product in general. However, it was only in 1957 and in 1958 that the situation radically changed. Indeed, in 1957 Grothendieck published his landmark "Sur quelques points d'algebre homologique" in which categories are used intrinsically to define and construct more general theories which are then applied to specific fields, in particular, in the following years, algebraic geometry, and in 1958 Kan published "Adjoint functors" and showed that the latter concept subsumes the important concepts of limits and colimits and also captures crucial conceptual situations. From then on, category theory became more than a convenient language.

Indeed, in the sixties, category theory developed rapidly, mainly in the context of algebraic geometry, algebraic topology and universal algebra. One of the main features which appears on the scene then and which is the direct development of Grothendieck's work is the characterization of abstract categories in which various branches of mathematics can be developed. For instance, what is called an abelian category is given by categorical conditions, usually the existence of certain adjoint functors, which garantee the development, in this case, of a large portion of homological algebra. In the same period, and this time mostly under the influence of William Lawvere, the idea that category theory could be used as a foundation of mathematics came to be considered and developed seriously. This approach culminated in the development of an other idea due to Grothendieck and his school: the notion of a topos.

Even though the concept of a topos was presented in the 1960s, it was certainly Lawvere & Tierney's work on the elementary axiomatization of the concept, published in the early 1970s, which gave to the notion its foundational status and impetus. Very roughly, a topos is a category which also possess a rich logical structure, rich enough to develop most of "ordinary mathematics", that is, most of what is taught in an undergraduate degree in mathematics. But it is also a generalized topological space and thus provides a direct connection between logic and geometry. The 1970s saw the development and application of the concept. (For more on the history of topos theory, see McLarty 1992.)

Finally, from the 1980s to this day, category theory found new applications. On the one hand, it now has many applications to theoretical computer science where it has firm roots and contributes, among other things, to the development of the semantics of programming and the development of new logical systems. On the other hand, its applications to mathematics are becoming more diversified and it even touches upon theoretical physics where higher-dimensional category theory, which is to category theory what higher-dimensional geometry is to plane geometry, is used in the study of knots.

Philosophical Significance

Category theory challenges philosophers in two non-exclusive ways. On the one hand, it is certainly the task of philosophy to clarify the general epistemological status of category theory and, in particular, its foundational status. On the other hand, category theory can be used by philosophers in their exploration of philosophical and logical problems. These two aspects can be illustrated briefly in turn.

Category theory is now a common tool in the toolbox of mathematicians. That much is clear. It is also clear that category theory unifies and provides a fruitful organization of mathematics. Given these simple facts, it remains to be seen whether category theory should be "on the same plane", so to speak, with set theory, whether it should be considered seriously as providing a foundational alternative to set theory or whether it is foundational in a different sense altogether. (The same question applies, in fact and even with more force, to topos theory, but we will unfortunately ignore this area here.) Arguments in favor of category theory and arguments against category theory as a foundational framework have been advanced. (See Marquis 1995 for a quick overview and a proposal.) This is in itself a complicated issue which is rendered even more difficult by the fact that the foundations of category theory itself still have to be clarified. Given that most of philosophy of mathematics of the last 50 years or so has been done under the assumption that mathematics is more or less set theory in disguise, the retreat of set theory in favor of category theory would necessarily have an important impact on philosophical thinking.

The use of category theory for logical and philosophical studies is already well underway. Indeed, categorical logic, the study of logic with the help of categorical means, has been around for about 30 years now and is still vigorous. On that front, many important results have been obtained but are still largely ignored by philosophers. Suffice it to mention the generalization of Kripke-Beth semantics for intuitionistic logic to sheaf semantics by Joyal, the discovery of the so-called geometric or coherent logic, whose practical and conceptual significance still has to be exposed, the notion and theorems of strong conceptual completeness, the geometric proofs of the independence of the continuum hypothesis and other strong axioms of set theory, the development of synthetic differential geometry which provides an alternative to standard and non-standard analysis, the construction of the so-called effective topos in which every funtion on the natural numbers is recursive, categorical models of linear logic, modal logic and higher-order type theories in general and the development of a graphical syntax, called sketches. Category theory also provides relevant information to more general philosophical questions. For instance, Ellerman 1987 has tried to show that category theory constitutes a theory of universals which has properties radically different from set theory considered as a theory of universals. If we move from universals to concepts in general, we can see how category theory could be useful even in cognitive

science. Indeed, Macnamara and Reyes have already tried to use categorical logic to provide a different logic of reference. (See, for instance, Macnamara & Reyes 1994.) McLarty, Marquis and Awodey have tried to show how it sheds an interesting light on structuralists approach to mathematical knowledge.

Thus, category theory is philosophically relevant in many ways and which will undoubtedly have to be taken into account in the years to come.

Holes

Holes are an interesting case-study for ontologists and epistemologists. Naive, untutored descriptions of the world and explanations of facts in the world often make essential reference to holes. A hole explains why water flowed out of the reservoir. A colander wouldn't be what it is, without all those holes in it. It is because there is a hole that somebody has the impression of seeing a hole. Yet it might be argued that commitment to these entities is only illusory:

Problems with Holes

1. For any explanation of a physical interaction that might be offered in terms of holes, there must be some accompanying explanations that invoke material objects; but then, it seems that these explanations alone could be enough. That water flowed out of the reservoir is explained by a number of facts about water flow and the way it can be confined, and at no point in these explanations need the concept of a hole appear; instead, one might happen to talk of the shape of the reservoir.

2. Locke implied that a causal theory of perception is incompatible with the perception of holes; since

holes are not material they cannot be the source of any causal flow. (This might be considered an instance of the argument ad 1.) That we do have the impression of perceiving holes should then be considered a sort of systematic illusion. (Unless one rejects causal accounts of perception.)

Theories of Holes

If, on account of such concerns, holes are not taken at face value, a number of options are available.

> (a) Holes do not exist. This requires at least a systematic way of paraphrasing every hole-committing sentence by means of a sentence that does not refer to or quantify over holes. (The donut is holed, but there is no hole in it). Provided the language contains all the necessary shape-predicates, this might well be a favourable strategy: after all, holes are a paradigm example of nothings.
>
> (b) Holes exist, but they are something else. For instance, they are (parts of) material objects, say, hole-linings or hole-surrounds. This calls for an account of the altered meaning of certain predicates or prepositions. (What would ‘inside’ and ‘outside’ mean? What would it mean to ‘enlarge’ a hole?)

Or holes are negative, missing parts. On this account, a donut would be a sort of mereological sum of a pie and a mysterious missing bit in the middle. Or again, holes are not categorically homogeneous with their hosts. They are not particulars, but relations between a material object and a volume of space. (But now how can we account for the shape and size of holes? Relations do not have shapes and sizes.)

On the other hand, the possibility remains that holes be taken for what they are. They are full-fledged countable entities, like stones and chunks of cheese. But unlike stones and chunks of cheese, holes are ontologically parasitic: they are always in or through something else, and cannot be detached from their hosts. Holes are immaterial; localized at --but not identical with-- regions of space; fillable; and somehow causally liable. They are subject to part/whole structures. Yet holes are always in one piece--there is no such thing as half a hole.

Holes are topologically assorted: superficial hollows are distinguished from internal cavities; straight perforations are distinguished from knotted tunnels. But the hole realist will not fail to notice the unity of this assortment. These are all species of the same genus. Thus the underlying topology must depart from the basic account of handlebodies and calls for a direct analysis of their topological complements. Look at the donut, but keep an eye on the hole--or on what could fill it.

Private Language

The idea of a private language was made famous in philosophy by Ludwig Wittgenstein, who in section 243 of his book *Philosophical Investigations* explains it thus: ‘The words of this language are to refer to what can be known only to the speaker; to his immediate, private, sensations. So another cannot understand the language.’ [My translation.] This is not intended to cover (easily imaginable) cases of recording one's experiences in a personal code, for such a code, however obscure in fact, could in principle be deciphered. What Wittgenstein had in mind is a language conceived as *necessarily* comprehensible only to its single originator because the things which define its vocabulary are necessarily inaccessible to others.

Immediately after introducing the idea, Wittgenstein goes on to argue that there cannot be such a language. The importance of drawing philosophers' attention to a largely unheard-of notion and then arguing that it is unrealizable lies in the fact that an unformulated reliance on the possibility of a private language is arguably essential to mainstream epistemology, philosophy of mind and metaphysics from Descartes to versions of the representational theory of mind which have been prominent in late twentieth century cognitive science.

Section Links:

Overview: Wittgenstein's Argument and its Interpretations

Wittgenstein's main attack on the idea of a private language is contained in sections 244-271 of

Philosophical Investigations. These passages, especially those from section 256 onwards, are now commonly known as ‘the private language argument’, despite the fact that he brings further considerations to bear on the topic in other places in his writings.

The argument is quickly summarized. The conclusion is that a language in principle unintelligible to anyone but its originating user is impossible. The reason for this is that such a so-called language would, necessarily, be unintelligible to its supposed originator too, for he would be unable to establish meanings for its putative signs.

Nevertheless, there has been fundamental and widespread disagreement over the details, the significance and even the intended conclusion of the argument, let alone over its soundness. Some of this disagreement has arisen because of the notorious difficulty and occasional elusiveness of Wittgenstein's own text (sometimes augmented by problems of translation). For example, some philosophers have questioned the very existence in the relevant passages of a unified structure properly identifiable as a sustained argument. But much derives from the tendency of philosophers to read into the text their own preconceptions without making them explicit and asking themselves whether its author shared them. Some commentators, for instance, supposing it obvious that sensations are private, have interpreted the argument as intended to show they cannot be talked about; some, supposing the argument to be an obvious but unsustainable attempt to wrest special advantage from scepticism about memory, have maintained it to be unsound because it self-defeatingly implies the impossibility of public discourse as well as private; some have assumed it to be a direct attack on the problem of other minds; some have claimed it to commit Wittgenstein to behaviourism; some have thought it to imply that language is, of necessity, not merely potentially but actually social.

The early history of the secondary literature is largely one of disputation over these matters. Yet what these earlier commentators have in common is significant enough to outweigh their differences and make it possible to speak of them as largely sharing an Orthodox understanding of the argument. Since the publication in 1982 of Saul Kripke's definitely unOrthodox book, however, in which he suggested that the argument poses a sceptical problem about the whole notion of meaning, public or private, disputation conducted by Orthodox rules of engagement has been largely displaced by a debate on the issues arising from Kripke's interpretation. Both debates, though, show a tendency to proceed with only the most cursory attention to the original argument which started them off.

This rush to judgment about what is at stake, compounded by a widespread willingness to discuss commentators' more accessible accounts of the text rather than confront its difficulties directly, has made it difficult to recover the original from the accretion of more or less tendentious interpretation which has grown up around it. Such a recovery is one of the tasks attempted in this article.

The Significance of the Issue

The issue's significance can be seen by considering how the argument is embedded in the structure of *Philosophical Investigations*. Immediately prior to the introduction of the argument (sec. 241 f.), Wittgenstein suggests that the existence of the rules governing the use of language and making communication possible depends on agreement in human behaviour -- such as the uniformity in normal human reaction which makes it possible to train most children to look at something by pointing at it. (Unlike cats, which react in a seemingly random variety of ways to pointing.) One function of the private language argument is to show that not only actual languages but the very possibility of language and concept formation depends on the possibility of such agreement.

Another, related, function is to oppose the idea that metaphysical absolutes are within our reach, that we can find at least part of the world as it really is in the sense that any other way of conceiving that part must be wrong (cf. *Philosophical Investigations* p. 230). Philosophers are especially tempted to suppose that numbers and sensations are examples of such absolutes, self-identifying objects which themselves force upon us the rules for the use of their names. Wittgenstein discusses numbers in earlier sections on rules (185-242). Some of his points have analogues in his discussion of sensations, for there is a common underlying confusion about how the act of meaning determines the future application of a formula or name. In the case of numbers, one temptation is to confuse the mathematical sense of ‘determine’ in which, say, the formula $y = 2x$ determines the numerical value of y for a given value of x (in contrast with $y > 2x$, which does not) with a causal sense in which a certain training in mathematics determines that normal people will always write the same value for y given both the first formula and a value for x -- in contrast with creatures for which such training might produce a variety of outcomes (cf. sec. 189). This confusion produces the illusion that the result of an actual properly conducted calculation is the inevitable outcome of the mathematical determining, as though the formula's meaning itself were shaping the course of events.

In the case of sensations, the parallel temptation is to suppose that they are self-intimating. Itching, for example, seems like this: one just feels what it is directly; if one then gives the sensation a name, the rules for that name's subsequent use are already determined by the sensation itself. Wittgenstein tries to show that this impression is illusory, that even itching derives its identity only from a sharable practice of expression, reaction and use of language. If itching were a metaphysical absolute, forcing its identity upon me in the way described, then the possibility of such a shared practice would be irrelevant to the concept of itching: the nature of itching would be revealed to me in a single mental act of naming it (the kind of mental act which Russell called ‘acquaintance’); all subsequent facts concerning the use of the name would be irrelevant to how that name was meant; and the name could be private. The private language argument is intended to show that such subsequent facts could not be irrelevant, that no names could be private, and that the notion of having the true identity of a sensation revealed in a single act of acquaintance is a confusion.

The suggestion that a language could be private in the way described appears most openly in the second of Bertrand Russell's published lectures ‘The Philosophy of Logical Atomism’, where Russell says:

> In a logically perfect language, there will be one word and no more for every simple

> object, and everything that is not simple will be expressed by a combination of words, by a combination derived, of course, from the words for the simple things that enter in, one word for each simple component. A language of that sort will be completely analytic, and will show at a glance the logical structure of the facts asserted or denied. ... A logically perfect language, if it could be constructed, would not only be intolerably prolix, but, as regards its vocabulary, would be very largely private to one speaker. That is to say, all the names that it would use would be private to that speaker and could not enter into the language of another speaker.
>
> ... A name, in the narrow logical sense of a word whose meaning is a particular, can only be applied to a particular with which the speaker is acquainted, because you cannot name anything you are not acquainted with.
>
> ... One can use ‘this’ as a name to stand for a particular with which one is acquainted at the moment. We say ‘This is white’. ... But if you try to apprehend the proposition that I am expressing when I say ‘This is white’, you cannot do it. If you mean this piece of chalk as a physical object, then you are not using a proper name. It is only when you use ‘this’ quite strictly, to stand for an actual object of sense [i.e. a sense-datum], that it is really a proper name. And in that it has a very odd property for a proper name, namely that it seldom means the same thing two moments running and does not mean the same thing to the speaker and to the hearer.
>
> ... [I]n order to understand a name for a particular, the only thing necessary is to be acquainted with that particular. When you are acquainted with that particular, you have a full, adequate and complete understanding of the name, and no further information is required.

Although Wittgenstein does not explicitly say so, it is likely that this is the inspiration of his argument: his writing is marked in many places by criticism of Russell.

But the idea of a private language is more usually hidden: the confusions supposed to belong to it allegedly underlie a range of articulated philosophical notions and theories, without themselves being so articulated. The argument is thus perhaps most profitably read, not as refuting any particular theory, but as removing the motivation for considering a range of apparently independent or even competing theories along with their associated tasks, problems and solutions.

For example, a still very common idea, often attributed to John Locke and openly embraced by Jerry Fodor in the nineteen seventies, is that interpersonal spoken communication works by speakers' translation of their internal mental vocabularies into sounds followed by hearers' re-translation into their own internal vocabularies. Again, Descartes considered himself able to talk to himself about his experiences while claiming to be justified in saying that he does not know (or not until he has produced a reassuring philosophical argument) anything at all about an external world conceived as something

independent of them. And he and others have thought: while I may make mistakes about the external world, I can infallibly avoid error if I confine my judgments to my immediate sensations. (Compare *The Principles of Philosophy*, I, 9.) Again, many philosophers, including John Stuart Mill, have supposed there to be a problem of other minds, according to which I may reasonably doubt the legitimacy of applying, say, sensation-words to beings other than myself.

In each of these examples, the implication is that the internal vehicle of my musings could in principle be private: for these problems and theories even to make sense, sharability must be irrelevant to meaning and it must be at least conceivable that my knowledge, even my understanding, is necessarily confined to my own case. This is especially clear with Descartes: for his sceptical question to be raised without being immediately self-defeating, he must hold it possible to identify his experiences inwardly -- where 'inwardly' means without relying on resources supplied by his essential embodiment in a world whose existence is independent of his own mind and accessible to others (e.g. such resources as the concepts acquired in a normal upbringing). The question which accordingly looms large in the private language argument is: How is this identification of one's experiences to be achieved?

[Return to Section Links]

The Private Language Argument Expounded

Preliminaries

Having introduced the idea of a private language in the way already quoted, Wittgenstein goes on to argue in a preliminary discussion (sections 244-255) that there are two senses of 'private' which a philosopher might have in mind in suggesting that sensations are private, and that sensations as they are talked about in natural languages (such as English and German) are in fact private in neither of them. He then turns, at section 256, to the question whether there could be a private language at all. He continues to talk of sensations, and of pain as an example, but one should remember that these are not *our* sensations, the everyday facts of human existence, but the sensations of something like a Cartesian soul (perhaps one associated with a physical body, as indicated in sections 257 and 283), something which has no publicly available life and whose "experiences" are accordingly private -- that is, they are supposed exemplars of *philosophical accounts* of the everyday facts of human existence, not those facts themselves. So in section 256 Wittgenstein suggests that one cannot arrive at the idea of a private language by considering a natural language: natural languages are not private, for our sensations are expressed. But neither can we arrive at the idea by starting with a natural language and just subtracting from it all expression of sensations (temporary paralysis is clearly not in question), as he considers next, for as he says in section 257, even if there could be language in such a situation as this where teaching is impossible, the earlier argument of *Philosophical Investigations* (sections 33-35), concerning ostensive definition, has shown that mere "mental association" of one thing with another is not alone enough to make the one into a name of the other. Naming one's sensation requires a place for the new word: that is, a notion of sensation. The attempt to name a sensation in a conceptual vacuum merely raises the

questions of what this business is supposed to consist in, and what is its *point*. But, for the sake of getting to the heart of the matter, Wittgenstein puts the first of these questions on one side and pretends that it is sufficient for the second to imagine himself in the position of establishing a private language for the purpose of keeping a diary of his sensations.

However, to investigate the possibility of the imagined diary case by exploring it from the inside (the only way, he thinks, really to expose the confusions involved) requires him to use certain words when it is just the right to use these words which is in question. Thus he is forced to mention in section 258 actions like ostensive definition, concentrating the attention, speaking, writing, remembering, believing and so on, in the very process of suggesting that none of these can really be done in the situation under consideration (section 261).

This difficulty has often gone unnoticed by commentators on the argument, with particularly unhappy results for the understanding of the discussion of the diary example. Fogelin, for instance, a paradigm representative of Orthodoxy, treats this as a case where *he himself*, a living embodied human being, keeps a diary and records the occurrences of a sensation which he finds it impossible to describe to anyone else. But we are not to assume that the description of the keeping of the diary is a description of a possible or even ultimately intelligible case. In particular, we are not to think of such a human being's keeping a real diary, but of something like the Cartesian internal equivalent. It is thus vital to the argument that the diary case is presented in the first person, without our pressing the question, ‘Who is speaking?’ At this stage we are simply not to worry about whether the diary story ultimately makes sense or not. But the fact that it may not make sense must be remembered in reading what follows, which in strictness should constantly be disfigured with scare quotes. (I shall, as I have already, occasionally supply them as a reminder, reserving double quotes for this purpose.)

To summarize the argument's preliminary stage: In section 256 Wittgenstein asked of the "private language", ‘*How* do I use words to stand for my sensations?’, and reminded us in section 257 that we cannot answer ‘As we ordinarily do’. So this question, which is the same question as ‘How do I obtain meaning for the expressions in a "private language"?’ is still open; and the answer must be independent of our *actual* connections between words and sensations. In the attempt to arrive at an answer, and explore the question in its full depth, he temporarily allows the use of the notions of sensation and diary-keeping (despite the objections of section 257), and imagines himself in the position of a private linguist recording his sensations in a diary. The aim is to show that even if this concession is made, meaning for a sensation-word still cannot be secured and maintained by such a linguist. The crucial central part of the argument begins here, at section 258.

The Central Argument

Wittgenstein points out of the diary case ‘first of all that a definition of the sign cannot be formulated’. (The translation here obscures the reason why. Wittgenstein's word is ‘aussprechen’, better translated as ‘expressed’ than ‘formulated’: the point follows by definition from the fact that the case is one where the definition is private.) So if meaning is to be obtained for the "sign", this must be achieved through a

private exercise of ostensive definition, where I concentrate on the sensation and produce the sign at the same time. But if this exercise is to be genuine and successful ostensive definition, it must *establish* the connection between sign and sensation, and this connection must *persist*. As Wittgenstein says, ‘"I impress [the connection] on myself" can only mean: this process brings it about that I remember the connection *right* in the future’. For I do not define anything, even to myself let alone anyone else, by merely attending to something and making a mark, unless this episode has the appropriate consequences.

Interlude: the Rejection of Orthodoxy

At this point we should suspend our exposition of the argument, in order to examine closely the remark ‘this process brings it about that I remember the connection *right* in the future’.

This remark has usually been interpreted as a demand that, for the sign ‘S’ to have been given a meaning, it must always figure thereafter (if used affirmatively and sincerely) as a true statement: that is, I must use the sign ‘S’ affirmatively only when I really do have the sensation S. And it has usually been thought that the subsequent argument concerns the adequacy of memory to ensure that I do not later misidentify my sensations and call a different kind of sensation ‘S’ in the future. This account of the argument and its history is summed up by Anthony Kenny as follows:

> Many philosophers have taken ‘I remember the connection right’ to mean ‘I use "S" when and only when I really have S’. They then take Wittgenstein's argument to be based on scepticism about memory: how can you be sure that you have remembered aright when next you call a sensation ‘S’? ...
>
> Critics of Wittgenstein have found the argument, so interpreted, quite unconvincing. Surely, they say, the untrustworthiness of memory presents no more and no less a problem for the user of a private language than for the user of a public one. No, Wittgenstein's defenders have said, for memory-mistakes about public objects may be corrected, memory-mistakes about private sensations cannot; and where correction is impossible, talk of correctness is out of place. At this point critics of Wittgenstein have either denied that truth demands corrigibility, or have sought to show that checking is possible in the private case too. (Kenny, pp. 191-192)

This interplay of criticism and defence characterizes the Orthodox interpretation of the argument. (See Fogelin, pp. 162-4, for a good example.) There seem to be at least two reasons why this interpretation should have become established. First, philosophers committed to the idea of a private language are generally looking for an arrangement in which mistakes of fact are impossible; that is, they are trying to overcome scepticism by finding absolute certainty. (Descartes is the example usually cited.) And this would make sceptical arguments appear to be natural weapons to use in reply to them. (See, e.g., Fogelin p. 153.) Secondly, it is plausible -- which is not the same as correct -- to suppose that one cannot be mistaken concerning the natures of one's present sensations, and a supposed proof that the idea of a private language entails that one is just as fallible on this subject as on any other could thus seem

crippling to that idea.

But, as Kenny first showed, the question of factual infallibility in future uses of the sign ‘S’ is not the issue. If we look closely at section 258, we see that ‘I remember the connection *right*’ refers to remembering a *meaning*, namely, the meaning of the sign ‘S’, not to making sure that I infallibly apply ‘S’ only to S's in the future. (Nor does the private language argument depend on taking the latter to be an effect of the former.)

The Central Argument Continued

Now that we are clearer about what the connection is which has to be remembered right, we can return to the exposition of the argument. I am to imagine that I am a private linguist. I have a sensation, and make the mark ‘S’ at the same time, as I might in an ordinary case introduce a sign by ostensive definition. Afterwards, I "believe" myself to have established a meaning for this sign ‘S’, and I now use it to judge that I am again experiencing the same sensation. What do I mean by ‘S’ on this second occasion? Wittgenstein considers two possible answers.

The First Answer

One of the answers is that what I mean by ‘S’ is just the sort of sensation I am now having. Of this Wittgenstein says merely:

> ... whatever is going to seem right to me is right. And that only means that here we can't talk about ‘right’.

The point is highly condensed. Here is a more explicit version. For there to be factual assertion, there must be the distinction between truth and falsehood, between saying what is the case and saying what is not. For there to be the distinction between truth and falsehood, there must be a further distinction between the source of the meaning, and the source of the truth, of what is said. Suppose that I confront some object and say of it ‘This is S’. If I must also appeal to this very object to explain the meaning of the sign ‘S’, I deprive my initial utterance of any claim to the status of factual assertion -- it becomes, at best, ostensive definition. (The ‘at best’ is important here, for the same reason that the diary example is not to be assumed genuinely possible.)

The Second Answer

The second answer Wittgenstein considers to the question of what I mean by ‘S’ is this: I mean by ‘S’, not this current sensation, but the sensation I named ‘S’ in the past. We have already seen, in Kenny's rejection of the Orthodox reading of the argument, that scepticism about memory has no place in the discussion of "private language"; the text simply does not support it. But at this point we must break with Kenny too. For according to his account the crucial claim becomes: ‘If it is possible for me to misremember my previous ostensive definition of "S", then I do not really know what "S" means.’ (See,

e.g., Kenny p. 194.) This is just conventional scepticism about memory extended to include meanings as well as judgments. And it is an elementary point of epistemology that knowing something does not obviously entail just as a result of the definition of knowledge that it is *impossible* for one to be wrong about that thing, only that one is not in fact wrong.

What has gone wrong? The answer is that Kenny's and the Orthodox accounts share an unnoticed assumption: that even in the circumstances of the "private language" there is actually an application of a sign to a private sensation by a private linguist. The problem as Kenny then conceives it is one of later remembering this earlier application in order that ‘S’ should have retained its meaning. The question then seems to be whether one's admittedly fallible memory is adequate for the maintenance of meaning. But why should this assumption be allowed? What entitles us to assume that a private linguist could even ostensively define his sign to himself in the first place? As we have seen, this is one of the matters in question; and sections 260 and 261 show that Wittgenstein was not prepared to let an argument in favour of private language proceed from this assumption. In these two sections Wittgenstein reminds us that his arguments in the earlier sections (e.g. 33-35) of *Philosophical Investigations* showed that ostensive definition was not achieved by any performance unless certain circumstantial conditions are fulfilled; and nothing about the diary case as so far described shows them to be fulfilled. It is only later (sections 270-271) that Wittgenstein imagines a partial fulfilment of them, and the result there is to render the language public.

One cause of the muddle is Wittgenstein's insistence that there must be a distinction between obeying a rule and merely thinking that one has. This does not result, as the Orthodox have supposed, in a demand for, and eventual rejection of, ‘memory-infallibility in a private language’: demand and rejection being based respectively on the grounds that without infallibility one could always be going wrong and would never know if one were, and with infallibility one would collapse the distinction between obeying a rule and merely thinking one was obeying it. Rather, the argument is this. The private linguist cannot legislate a meaning for a sign by "private ostensive definition" *merely* -- for this has to establish a technique of using the sign (section 260). The technique cannot function by means of repeated "ostensive definitions", as we saw in examining the first answer, since this collapses the distinction between meaning and truth and thus destroys the possibility of making factual judgments. So the so-called "definition" has on some other basis to establish a constancy in use of the sign.

But this is just what is in question. What would be *constancy* here? What would *be* using the sign in the same way as before? How *was* the sign used in the first place? As there cannot be assumed to be a way of using the sign which the linguist succeeds even in determining, let alone establishing, and which is the correct way, independent of the linguist's later impression of the correct way, then a defender of "private language" would have to show that there was. It might now seem as if one could show this by appealing to the private linguist's memory. He simply remembers how he used the sign before. And this looks straightforward enough, because one thinks: he certainly did something before, for he remembers it. And we do not require his memory to be infallible. But the memory does at least have to be a *memory*: that is, accurate or not, it has to be of something determinate which existed independently of the memory of it; and the "memory" alone cannot bring such a thing into existence.

This is the argument of section 265, which has often been mistakenly given an epistemological interpretation. Again we cannot assume that there has been an actual table (even a mental one) of meanings in the case of the private linguist, a table which is now recalled and about which the linguist must rely on recall since the original has gone. Rather, as sections 260-264 show, there may be nothing determinate other than this "remembering of the table". So when we think that a private linguist could remember the meaning of ‘S’ by remembering a past correlation of the sign ‘S’ with a sensation, we are supposing what needs to be itself established -- that there was indeed some independent correlation to be remembered. Fallibility of memory, even of memory of meaning, is neither here nor there: the point is not that there is doubt *now* about the trustworthiness of memory, but that there was doubt *then* about the status of what occurred. And this original, *non*-epistemological, doubt cannot later be removed by "recollections" of a status inherently dubious in the first place. That is, if there was no genuine original correlation in the first place, a "memory" will not create one. But if, alternatively, we do not suppose that there was something independent of the memory to be remembered, again ‘what seems right is right’; the "memory" of the "correlation" is being employed to confirm itself, for there is no independent access to the "remembered correlation". (Not even the independent access that we have as posers of the example, since the question is, can we pose such an example? The typical mistake commentators make here is to disguise the problem by thinking of S in terms of some concept, such as *pain*, which they bring to the example themselves.) This is why Wittgenstein says (section 265), ‘As if someone were to buy several copies of the morning paper to assure himself that what it said was true’.

The Closing Stages

So far the argument has been conducted in terms of souls unrelated to bodies or related only to inert bodies. At section 269, however, it moves to examples where there is bodily behaviour but despite this there is still the temptation to think of private meanings for words independent of their public use. This suggests a further chance for a defender of the idea of a private language: that a private linguist might secure a meaning for his sign ‘S’ by correlating its private use with some public phenomenon. This would apparently serve to provide a function for the noting of ‘S’ in the diary (section 260) and thus give a place for ostensive definition, and would give as well a guarantee that there is some constancy in the linguist's use of the term ‘S’ independent of his impression of such constancy. Wittgenstein uses the example of the manometer in sections 270-271 to consider this idea, and his criticism of it is in effect that this method of securing meaning works, but that the secured meaning is public: the so-called "private object", even if there were such a thing, is revealed to be irrelevant to meaning. Presumably a defender of "private language" would hope that the example would work like this: if I keep saying, on the basis of my sensation, that my blood pressure is rising, and the manometer shows that I am right, then this success in judging my own blood pressure shows that I had in fact established a private meaning for the sign ‘S’ and was using the sign in the same way each time to judge that my sensation was the same each time. However, all the example really shows is that just thinking that I have the same sensation now as I had when my blood pressure rose formerly, can be a good guide to the rising of my blood pressure. Whether in some "private sense" the sensation was "actually the same" or not becomes completely irrelevant to the question of constancy in the use of ‘S’ -- that is, there is no gap between the actual nature of the sensation and my impression of it, and ‘S’ in this case could mean no more than ‘sensation of the rising of the blood pressure’; indeed, for all we are told of the sign's role, it could even mean

merely ‘blood pressure rising’.

Are the Orthodox Objections Met?

Does the ruling out of memory-scepticism as irrelevant to the private language argument mean that two associated Orthodox objections to it are likewise irrelevant? The first of these is that the argument, self-defeatingly, rules out a public language as well. The second is that the argument, equally self-defeatingly, rules out as impossible something perfectly conceivable: namely, the case of a so-called ‘Robinson Crusoe’, a human being who, unlike Defoe's original Crusoe, is isolated from birth but devises a language for his own purposes without his having first been taught another language by someone else. Wittgenstein's Orthodox defenders, faced with this second objection, looked to be on shaky ground, often being forced into the position of conceding that the argument did indeed exclude the case, but claiming (not very plausibly) that such a Crusoe is after all impossible so that the concession was not damaging.

The question as it concerns the first objection has already been answered. The supposed threat to public language arose entirely from the the claim that memory-scepticism could not be confined to the private case. But since scepticism concerning memory is no part of the argument, there is no reason to suppose that any question of such confinement arises, and thus there is no question of the argument's being self-defeating by excluding the possibility of something we know to be actual, i.e. the language we already have. Now showing the absence of any appeal to memory-scepticism involved transferring the burden of the argument from the question of whether or not an ostensive definition could be remembered or not to the question of whether there could be an ostensive definition in the first place.

This enables us to answer the question as it concerns the second objection. It is clear that an argument which has as its focus the question of ostensive definition is not committed to ruling out in advance all hypothetical cases of ‘Robinson Crusoes’. For there is no a priori barrier to imagining a form of life complex enough for us to be assured that a determinate ostensive definition had been accomplished by such a being. Such a Crusoe, unlike a private linguist, lives in a world independent of his impressions of it, and thus there could be definite occurrences in it which he could remember or forget; and some of those occurrences could be correlations of signs with objects. (There are, however, further complications here. See Canfield 1996.)

Kripke's Sceptical Wittgenstein

The Orthodox domination of the secondary literature on private language was largely ended by Saul Kripke's account of Wittgenstein's treatment of rules and private language, in which Wittgenstein appears as a sceptic concerning meaning. Kripke (p. 5) denies commitment to the identity of this sceptical figure with its historical source, and, appropriately, his account has spawned a literature of its own in which discussion often proceeds largely independently of the original private language argument: Kripke's

Wittgenstein, real or fictional, has become a philosopher in his own right, and for many people, it is not an issue whether the historical Wittgenstein's original ideas about private language are faithfully captured in this version. The complexities of the subsequent discussion of the philosophical -- as opposed to interpretative -- questions raised by Kripke's Wittgenstein need a separate article to themselves. (For a survey, see Boghossian.) All that will be settled here is the interpretative question.

Kripke's account resembles that given here in its rejection of Orthodoxy and in its emphasis on the logical priority of the discussion of rule-following to that of private language. It differs in the prominence it gives to the opening sentence of *Philosophical Investigations* section 201: ‘This was our paradox: no course of action could be determined by a rule, because every course of action can be made out to accord with the rule.’ Kripke says of this (p. 68), ‘The impossibility of private language emerges as a corollary of [Wittgenstein's] sceptical solution of his own paradox’. Wittgenstein himself immediately brushed this "paradox" aside in his very next paragraph: ‘It can be seen that there is a misunderstanding here ...’; but Kripke takes the paradox to pose a genuine and profound sceptical problem about meaning.

The example Kripke chooses to illustrate the problem is that of addition. What is it to grasp the rule of addition? The application of the rule is potentially infinite, and bizarre interpretations of the rule, as well as the standard one, are compatible with any finite set of applications of the usual sort such as 7 + 14 = 21. So what is it which makes it true that when I say ‘plus’ I mean the usual addition function and not some other? Kripke understands this question as containing a Humean problem to which, he claims, Wittgenstein gives a Humean, ‘sceptical’ solution. Kripke formulates the problem in two different ways.

The first way is this: ‘there is no fact about me that distinguishes my meaning a definite function by "plus" ... and my meaning nothing at all’ (p. 21). The absence of this fact, in Kripke's view, leads Wittgenstein to abandon the explanation of the meanings of statements like ‘By "plus", I meant addition’ in terms of truth-conditions, and to replace it with explanation in terms of assertibility-conditions, which involve actual (not merely potential) community agreement. (Hence the claim that this is a ‘sceptical solution’: Wittgenstein is supposed to concede to the sceptic the absence of truth-conditions for such statements.) This agreement, on Kripke's account, legitimizes the assertion that I meant addition by ‘plus’ despite there having been no fact of the matter.

This requirement of community agreement for meaning obviously rules out the possibility of private language immediately, thereby making the argument of *Philosophical Investigations* sections 256-271 superfluous. This superfluity makes for an odd reading of the text; and the oddness is highlighted by the observation that this first formulation of the sceptical problem relies on Kripke's assumption that we have some idea of what a fact is, independent of a statement's being true. For one of the themes of *Philosophical Investigations* is that there is no such idea, that the only route to the identification of facts is through the uses of the expressions in which those facts are stated, uses which give us the truth-conditions. These uses are often very different from what we would expect -- hence the impression that truth-conditions are lacking -- and it is a matter of some philosophical difficulty to see them clearly.

The other formulation of the problem is this (Kripke p. 62): ‘Wittgenstein questions the nexus between

past "intention" or "meanings" and present practice: for example, between my past "intentions" with regard to "plus" and my present computation ... .' The idea is that my grasp of the rule governing the use of 'plus' does not determine that I shall produce a unique answer for each of indefinitely many new additions in the future. The impression that something is missing here, though, is a result of just that kind of confusion about determination identified in the section headed 'The Significance of the Issue' above.

Kripke's account of the private language argument is thus vitiated by his unargued reliance on ideas which Wittgenstein argued against. This of course does not show that he has not hit upon a new and more interesting notion of private language than that expounded here.

Stanford Encyclopedia of Philosophy

How to Cite This Encyclopedia

To cite the *Stanford Encyclopedia of Philosophy*, we recommend the following bibliographic format, which you may need to adapt to the meet the style requirements of the publication for which you are writing.

Typically, users read the current version of each online entry. This is the version you reach directly from our Table of Contents. However, because Encyclopedia entries are subject to periodic revision, it is more appropriate to cite the most recent archived version. When you quote from an entry, it is particularly important to cite an archived version. Be sure to verify that the passage you are quoting matches what is in the archived version.

If the material you wish to cite has not been archived (because the entry is new or has been recently modified), you should, if possible, wait for the next archived version of the Encyclopedia. Fixed editions of the Encyclopedia are created and archived every three months, on the 21st of September, December, March, and June.

As an example, you would cite Andrew Irvine's entry on Bertrand Russell by finding the most recent archived edition containing this entry. Your citation might look like this:

> Irvine, A., "Bertrand Russell", *The Stanford Encyclopedia of Philosophy* (Fall 1999 Edition), Edward N. Zalta (ed.), URL = http://plato.stanford.edu/archives/fall1999/entries/russell/

Note that the above URL ends in the name "russell" followed by a slash "/". "russell" is the name of the directory which contains the entry. The filename of the entry itself is "index.html" (indeed, all the entries in the Encyclopedia are named "index.html"). However, you need not include the entry filename at the end of the URL. By default, index.html is displayed when a web browser requests a URL such as the one displayed above.

If you require other kinds of bibliographic information, you may find the following facts helpful.

- Title: *The Stanford Encyclopedia of Philosophy*
- Principal Editor: Edward N. Zalta
- World Wide Web URL: http://plato.stanford.edu/
- Publisher:

  The Metaphysics Research Lab
  Center for the Study of Language and Information

Stanford University
Stanford, CA 94305-4115

- International Standard Serial Number: ISSN 1095-5054
